Turning to a consideration of the exhibits, it may be noted that although the absence of specimen plants marred the completeness of the Exhibition in one point of view they were not much missed, as few could regret the absence of formally trained specimens when inspecting the free and beautiful grouping of decorative plants. The groups were without doubt a most striking feature of the Exhibition. The first to be observed on entering the conservatory was that from Mr. Turner, Royal Nurseries, Slough. It was not large, but well arranged, and presented an effective appearance. The plants were in good condition, with foliage well down to the pots. Mr. G. Stevens, St. John's Nursery, Putney, London, S.W., had a larger collection, in which Pompons were freely—perhaps too freely—employed; the back Japanese and incurved included some fine blooms. Baron Schröder, The Dell, Staines (gardener, Mr. H. Ballantine), had taller plants bearing larger blooms, more noteworthy for the quality of the flowers than the general effect of the group. Elaine, Avalanche, Middle. Lacroix, Madame J. Laing, Bonnington, and Criterion were finely shown amongst others. A group exclusively composed of Japanese came from the Royal Horticultural Society's Gardens, and showed the free, graceful character of this beautiful section. Messrs. W. Fromow & Sons, Sutton Court Nursery, Chiswick, had a loosely arranged group not quite up to their best standard, and perhaps marred by a fear of overcrowding carried to extremes. Freely branched, well-flowered plants, irregularly arranged, represented the Royal Gardens, Kew, and the remaining groups comprised separate collections of incurved, Pompon, Anemone, single, reflexed, and Japanese reflexed from the Society's Gardens, all tastefully arranged and presenting a very bright and cheerful effect.

Collectively considered the cut flowers formed a splendid feature, covering the side stages all round the huge vinery. Far the most interesting class was that for flowers of all sections, not more than three blooms of any large variety in a bunch. Mr. E. Molyneux, gardener to W. H. Myers, Esq., Swanmore Park, Bishop's Waltham, had a splendid collection, reflecting the utmost credit on him. Amongst the incurved were

medium sized, beautifully finished blooms of Empress of India, Lord Alcester, Miss M. A. Haggas, Jeanne d'Arc, Princess of Wales, Violet Tomlin, and Golden Queen of England, but all were admirable flowers, and formed a capital stand. The reflexed were also extremely fine, King of the Crimson and the Christines, also Phidias and Cullingfordi, were excellent. Amongst the large Anemone flowered Fleur de Marie, Glück, Grand d'Alveole, Mdle. Cabrol, and Nelson were extremely good. The Japanese were best represented by Etoile de Lyon, Mdle. Lacroix, Avalanche, Edwin Molyneux, and Condor. Pompons and Anemone Pompons were a neat and pleasing display, and the singles were very bright, White Perfection, Mary Anderson, Admiral Sir T. Symonds, and Mrs. Le Moutt being particularly attractive. Messrs. J. Laing and Sons, Forest Hill, London, S.E., had stands of Japanese, incurved and reflexed, in good condition, the first named including a grand bloom of Etoile de Lyon. Mr. R. Owen, Castle Hill, Maidenhead, arranged his flowers in bunches in large receptacles instead of on stands. The formed a very free, bright, and fresh display, including Japanese in great variety, Pompons and singles also being extensively employed. Mr. C. J. Salter, gardener to T. B. Haywood, Esq., Woodhatch Lodge, Reigate, had several stands of remarkably neat blooms. Amongst the Japanese Jeanne Délaux, Sunflower, Mons. Astorg, Fimbriatum, and L'Adorable were very noteworthy. The incurved were small but admirably finished. The Anemone flowered were a beautiful display. R. Owen, pure snow white, was extremely beautiful, surpassing Lady Margaret and Fleur de Marie. J. Thorpe, jun., and Mrs. A. Lowe were also very good. Messrs. H. Cannell & Sons, Swanley, Kent, had a very extensive collection, comprising no less than 260 varieties, and contributing in itself a great feature of interest. The blooms were not regularly disposed in stands, but placed in small stone bottles and tastefully blended. It was difficult to pick out individual examples amongst so many of a meritorious character, but some were of remarkable size.

Incurved in twenty-four varieties were staged by Mr. Berry, The Gardens, Roehampton House, Roehampton, who had small but fresh neat blooms. Mr. Wildsmith, gardener to the Hon. E. L. Shaw-Lefevre, exhibited twelve (with a twenty-four card), these comprising good blooms of Princess of Wales, Jeanne d'Arc, Lord Alcester, and Lord Wolseley, but somewhat rough.

A capital stand of twenty-four Japanese came from Mr. Fyfe, gardener to Lord Wantage, Overstone Park, Northampton. Album Fimbriatum, Edwin Molyneux, Moonlight, Florence Percy, and Elaine were good. Mr. Wills, gardener to Mrs. Pearce, The Firs, Bassett, Southampton, and Messrs. Clibran, Altrincham, also had good stands of twenty-four, the blooms being of good size, fresh, and well coloured. Mr. Pope, The Gardens, Highclere Castle, Newbury, also exhibited. Stands of twelve Japanese came from Mr. R. Falconer Jameson, Hessel, Hull; and Wildsmith. The former's flowers were large and fine, but one or two a little the worse for their journey. Mr. Wildsmith's blooms were very fresh.

Reflexed were shown in capital condition by the last named. Cullingfordi was very richly coloured, King of Crimson large and fine, Cloth of Gold and Amy Furze also good. Mr. C. Gibson, gardener to J. Wormald, Esq., Morden Park, Surrey, had a very neat and pleasing stand of Pompons, in which Cendrillon, Black Douglas, Prince of Orange, and Marabout were noteworthy. Messrs. Paul & Son, The Old Nurseries, Cheshunt, had a beautiful stand of large Anemone-flowered, comprising a superb bloom of Sabine, and excellent flowers of J. Thorpe junior, Nelson, Jeanne Marty, Nelson, and Souvenir de Madame Blandinières.

Several classes were provided for Japanese and incurved, one colour only in a stand. Mr. Berry showed Empress of India as white incurved, a smooth, level lot. In the corresponding yellow class Mr. Molyneux had a magnificent stand of Golden Empress of India, every bloom large, well built, solid, smooth, fresh, and superbly finished. Mr. Berry also showed this variety with Emily Dale. White Japanese formed a pleasing display. Mr. Berry had Mdle. Lacroix, Maiden's Blush, and Avalanche in capital condition; Mr. Falconer Jameson, Avalanche, Mons. Astorg, Florence Percy, and Elaine; Mr. Doughty, gardener to Mrs. Tomlin, Cranbrook, Kent, a beautiful stand of Elaine. Mr. Burnett, The Grange Gardens, Hillingdon, Uxbridge, had a good stand of Roi des Japonais in the orange or bronze class, a very fine lot of Val d'Andorre in the red and crimson class, and good blooms of Madame C. Audiguier and Madame J. Laing in the lilac or pink class.

Amongst the new Chrysanthemums exhibited were L'Automne, Etoile de Lyon, Alfred Lynes, Stanstead Surprise, President Hyde, Annie Clibran, Thomas Stevenson, and Jeanne Marty from Messrs. Clibran; Mrs. James Carter, Holborn Beauty (Japanese), and James Carter (decorative reflexed) from James Carter & Co., 237, High Holborn, London; Mrs. Bevan Edwards, yellow sport from Mr. R. Brocklebank, by Mr. Winkworth, gardener to R. Brocklebank, Esq., Childwall Hall, Liverpool; Yellow Pompon Alice Storey, by Mr. G. Stevens, Putney; Lady Pet (Japanese), sport from Madame J. Laing, by Mr. W. Heath, Hampton Manor Gardens; Mrs. Horril reflexed, sport from George Glenn (name of exhibitor not observable); Miss M. A. Haggas (incurved), Violet Tomlin (incurved), James Weston (Japanese Anemone), and Puritan (Japanese) from Mr. E. Molyneux; and, lastly, the remarkable white incurved variety illustrated on another page, Mrs. Alpheus Hardy, of which a plant bearing six blooms was exhibited by Mr. Ware of Tottenham, and one with a single flower by Mr. Appleby, Dorking. The awards had not been published on going to press, and the certificated varieties will be described in another issue.

Mr. Parker, Impney Gardens, Droitwich, exhibited a beautiful basket of blooms that had been grown out of doors in ordinary soil

against a wall, and merely protected from heavy rain by boards. They comprised many well-known exhibition sorts in very good condition, and had been cut on November 4th. The new "Jameson" exhibition spring cup support and name card holder were exhibited by Messrs. E. P. Dixon & Sons, Hull; Messrs. R. Beale & Co., New Southgate, London, N., showed examples of Chrysanthemum propagation by leaves and cuttings in their fertilising moss. There were some paintings of Chrysanthemums from the Royal Gardens, Kew, also dried specimens.

The Conference was opened by an address from Mr. T. B. Haywood, and papers were read by Messrs. Payne, Molyneux, Wright, and Hibberd, which will be referred to in a future issue.

BRIGHTON—Nov. 5th and 6th.

THE seventh annual Exhibition of the Brighton and Hove Chrysanthemum Society was held on Tuesday and Wednesday last in the Dome and Corn Exchange, near the Pavilion, and proved to be the best this flourishing young Society has yet held, both in quality and number of exhibits. Over 400 entries were received, and the competition in some of the classes was remarkably keen. For example, in the cup class there were no less than ten entries, or a total of nearly 500 blooms, constituting a show in itself. Other classes for cut blooms were also well filled, those for plants, fruit, and vegetables bringing many competitors, and assisting materially in increasing the interest of the Show. The groups of Chrysanthemums also constituted an important feature, and, arranged as they were round the sides of the Corn Exchange, they produced a good effect. The latter building is very spacious, and admirably adapted for the purpose, as, while allowing due space for the exhibits, it also affords ample room for the thousands of visitors during the evening. The Dome is a handsome building, of circular form, in which some of the cut flowers were placed, with specimen plants, and a grand group of Palms, Ferns, Cycads, and Chrysanthemums in front of the organ was one of the most effective examples of plant arrangement we have ever seen at an autumn show.

The schedule provided forty-six classes, besides eighteen special classes, in which the prizes were contributed by local and other friends of the Society. A total of about £120 was offered in prizes (besides the £10 silver cup in class 9), an increase on last year, warranted by the satisfactory state of the finances. Few societies start the year with a balance to their credit of £88, yet that was the position of the Brighton Society at the beginning of 1889, and it is probable that the Show here recorded may lead to an advance upon this substantial amount. Such a state of affairs indicates liberal local support and excellent management, and as the result of seven years' work it is most creditable to all concerned. The Secretary, Mr. Mark Longhurst, has assisted considerably in the development of the Society, his energy and business-like method of procedure, aided by a practical Committee, of which Mr. R. Miller is the able Chairman, having conducted largely to the present satisfactory condition.

Cut Blooms.—These classes constituted the great feature of the Show, and the leading class was that for forty-eight blooms, not less than thirty-six varieties, or more than two of one variety. This was open to all exhibitors, the first prize consisting of a silver cup value £10 and £7 in cash, the second prize £6, the third £3, and the fourth £2. The cup was offered under the conditions that if an exhibitor won it twice (not necessarily consecutively) it should become his property, but if it be won by three different exhibitors in the first three years the competition in the fourth year should be confined to them.

No less than ten exhibitors entered, and the array of blooms had a magnificent appearance; in fact we do not remember so fine an effect produced by one class. The Judges in this section (Messrs. G. Gordon and L. Castle) had a formidable task to perform, but the real contest laid between two competitors, and after a very careful examination and pointing, the first honours were accorded to Mr. W. Nevill, gardener to F. W. Flight, Esq., Cornstiles, Winchester, who had excellent blooms of the following varieties, very fresh, bright, clean specimens, and remarkably even throughout. *Incurved.*—Back row: Golden Queen of England, Empress of India, Golden Empress, Lord Wolseley, Lord Alcester, Golden Queen, Alfred Salter, and Golden Empress. Middle row: Jeanne d'Arc, Mrs. Shipman, Violet Tomlin, Miss Haggas, Princess of Wales, Lord Wolseley, Jeanne d'Arc, and Mrs. Shipman. Front row: Prince Alfred, Mrs. Heale, Mr. Brunlees, White Venus, John Salter, Lady Hardinge, Nil Desperandum, and Princess of Wales. *Japanese.*—Back row: Stanstead White, Val d'Andorre, Boule d'Or, Madame B. Pigny, Val d'Andorre, Ralph Brocklebank, M. Bernard, and Stanstead White, a grand corner bloom, the finest in the Show. Middle row: L'Or du Japon, Sarah Owen, Bertha Flight, Ralph Brocklebank, Stanstead Surprise, Boule d'Or, E. Molyneux, and a variety we missed. Front row: Mdle. Lacroix, Sunflower, M. J. Laing, Mars, Avalanche, Madame J. Laing, Mrs. J. Wright, and Mdle. Lacroix.

The second prize was adjudged to Messrs. J. & G. Drover, Fareham, who had admirable blooms, the Japanese being nearly equal to those in the first stand; the back row of incurved was also formed of heavy handsome blooms, but there was a falling off in the two front rows. The varieties were, however, so good that they are worth naming. They were arranged in the following order. *Incurved.*—Back row: Lord Alcester, Golden Queen, Lord Alcester, Queen of England, Empress of India, Alfred Salter, Empress of India, and Golden Queen. Middle row: C. Gibson, Princess Teck, Golden Empress, Nil Desperandum, Queen of England, Lord Wolseley, Golden Empress, and Nil Desperandum. Front row: Novelty, Prince Alfred, Cherub, Princess of Wales, Barbara, Jeanne d'Arc, Refulgence, and Eve. *Japanese.*—Back row: Carew Underwood, Boule

d'Or, Triomphe de la rue des Châlets, Monsieur J. M. Pigny, F. Marrouch, Carew Underwood, Boule d'Or, and Baronne de Prailly. Middle row: Gloriosum, Madame J. M. Pigny, E. Molyneux, G. Maclure, E. Molyneux, Madame Baco, Meg Merrilies, and Belle Paule. Front row: Madame Baco, J. Délaux, Mdle. Laeroix, Sarah Owen, Fimbriatum, J. Délaux, Madame C. Audiguier, and Florence Percy. The third prize was secured by Mr. C. Penfold, gardener to General Sir F. Fitzwygram, Bart., Leigh Park, Havant, who had capital blooms, fresh, bright Japanese, and neat even incurved. Mr. J. Hopkins, gardener to R. Thornton, Esq., J.P., High Cross, Framfield, was fourth, his Japanese being notable, the front row especially. The other stands were all good, and some of them well merited recognition had the prize list admitted it.

In other classes the competition was also close. The best twenty-four Japanese were shown by Mr. T. Glen, gardener to Mrs. Montefiore, Worth Park, who was first in that class, followed closely by Mr. G. Duncan, gardener to C. T. Lucas, Esq., Warnham Court, Horsham; Mr. M. Russell, gardener to D. C. F. Lewis, Esq., Henfield; and Mr. J. Hopkins, in the order named. Amongst twelve competitors with twelve Japanese Mr. A. Emery, gardener to R. W. Tweedie, Esq., Avoca, Eastbourne, won first honours with excellent blooms, and the same exhibitor secured a number of prizes in other classes throughout the Show. Mr. C. Sayers, gardener to Mrs. Cook, The Hall, Mitley, was second; and Mr. C. Fowler, gardener to Mrs. Hall, Henfield, third. Incurved were shown by Messrs. Emery, Sayers, Roberts, and Papworth, who took prizes in the order named, Mr. M. Russell having the first prize for the only collection of twenty-four incurved. Anemones were well shown by Mr. Phillips, gardener to Dr. Baker; Reflexed by Mr. S. Coleman; Pompons by Mr. Russell; and six Japanese, one variety, by Mr. Emery, who had Avalanche in good condition; Mr. Glen being second for the same variety, and Mr. Hopkins third with Val d'Andorre.

About seventeen groups of Chrysanthemums were staged in two classes, Mr. G. House, gardener to F. Mowatt, Esq., Withdean Hall, Patcham, taking premier honours in Class 1 (100 square feet), an effective group, in which Val d'Andorre and J. Délaux were freely used in contrast with white varieties. Mr. A. Fry, gardener to C. W. Catt, Esq., 52, Middle Street, Brighton, gained a similar place in Class 2 (60 square feet) with a bright arrangement. Other exhibitors and prizewinners in these classes were Messrs. Spottiswood, W. Miles, J. Tulley, F. Collis, and Meachen. Mr. A. Seutt, gardener to G. S. Jenkins, Esq., Franklands, Burgess Hill, had four excellent standard Chrysanthemums, gaining the first prize; Mr. Hill having the best pyramids.

To the other exhibits we cannot refer in detail this week, but in the fruit classes there was good competition, the principal winners being for Grapes Messrs. Duncan, Spottiswood, and Phillips; Apples, Messrs. Duncan, Harris, Bunney, Slidworthy; Pears, Spottiswood, Duncan, and Bunney. Vegetables also were well shown, as were table plants, Mignonette, Primulas, and Cyclamens.

Non-competing exhibits comprised a neat, tasteful group of Chrysanthemums and foliage plants, to which we shall refer again—Star and Crescents of Elaine and Ferns, with a group of miscellaneous plants. The admirable group in the Dome, from Mr. W. Balechin; also a collection of Apples. Mr. R. Miller had a group of Chrysanthemums, and Mr. A. Fry an interesting group of Orchids, Nepenthes, and Ferns. A large collection of Apples was sent from Messrs. Cheal & Son, and there were several other exhibits which cannot be noted this week.

GOSPORT.—OCTOBER 31ST.

THE honour of commencing the Chrysanthemum Exhibition season of this year fell to this thriving young Society, which opened a two days Show in the Thorngate Hall on the date named. As proving that the seasons change, it is an unusual fact that a public exhibition of Chrysanthemums should be held in October, this date being not the least too early, as evinced by the exhibits staged in the hall above named. Although not of large dimensions, it is light and capital for an exhibition of this kind. The arrangements were excellent. The groups of Chrysanthemums, of which there were nine, were arranged down one side of the hall, the specimen plants on the opposite side. Two tables running down the centre of the hall contained the cut blooms, table plants, &c., the whole reflecting credit upon Mr. Mitchell, the Secretary, and the Committee, of whom Mr. Groom is Chairman.

Cut Blooms.—These formed the most important part of the Exhibition, between seven and eight hundred being staged, and these were of even quality throughout, making a good display. Especially high in point of quality were the blooms staged by the cottagers, and in many cases they were superior to those staged by gardeners. The most important class was for twenty-four distinct varieties, twelve to be Japanese and the remainder incurved. Amongst four competitors the best came from Mr. A. Abrahams, gardener to T. H. Wilson, Esq., Hazelholt, Bishop's Waltham, who had a capital stand, the Japanese being large, solid, and of capital colour. The varieties were as follows:—Incurved—Back row: Lord Wolseley, Golden Queen of England, Alfred Salter, and Lord Alcester. Middle row: Empress of India, Golden Empress, Jeanne d'Arc, and Queen of England. Front row: Refulgens, Mrs. Heale, Mr. Bunn, and Mr. Brunlees. Japanese—Back row: Madame C. Audiguier, Avalanche, Baron de Prailly, and Boule d'Or. Middle row: Madame Laing, Edwin Molyneux, Meg Merrilies, and Ralph Brocklebank. Front row: Florence Percy, Peter the Great, Belle Paule, and F. Marrouch. Mr. W. Herrington, Beesom Street, Portsmouth, was a good second with large fresh Japanese, and very neat medium-sized incurved specimens. Edwin Molyneux, Mrs. J. Wright, Sunflower, and Criterion were the best in the former

section. Mrs. W. Shipman, Jardin des Plantes, and Jeanne d'Arc were the most noteworthy in the incurved. Mr. W. H. Gale, gardener to G. Cooke, Esq., Gosport, was a good third. In this stand was an uncommonly fine bloom of Condor, a large Japanese, with a faint tinge of blush running through the broad florets. Those competed in the class for eighteen Japanese, Mr. H. Gale winning easily. Sunflower, Condor, Mr. F. W. Burbidge, pure white; Jeanne Délaux, and Madame Baco were the best. Mr. G. Hawkins, gardener to E. Laphorne, Esq., Gosport, was second with smaller, but fresh blooms. For the same number of incurved distinct Mr. H. Gale continued his success by winning easily with small but neat blooms. Mr. F. Limburn, Gosport, was second. For twelve large Anemones Mr. Hawkins was the only exhibitor, staging good specimens of Lady Margaret, Grand d'Alvéole, George Sand, and a sport from the latter named George Hawkins, the centre deep yellow, the guard florets lemon, quite a promising variety. This exhibitor was an easy first in the class for twelve reflexed in not less than six varieties amongst five competitors, King of Crimsons, Cullingfordi, Cloth of Gold, and Peach Christine being the most noteworthy. Mr. W. H. Fay was second with small blooms. Mr. Gale was the only exhibitor in class 10, for twelve Japanese Anemone blooms, staging fresh well built samples of Fabian de Médiana, Sœur Dorothee Souille, Mdle. Cabrol, and Minnie Chate. For a stand of Anemone and Japanese Anemone in twelve blooms, Mr. C. Miller, gardener to Dr. Marlow, C.B., took first honours with Thorpe, jun., Margaret Villageoise, Miss Annie Lowe, and George Sand as some of the best. For the best Japanese and incurved, single blooms shown in glasses, Mr. G. Hawkins easily gained first honours with solid blooms of Avalanche and Prince Alfred. This exhibitor followed up his previous success by taking first honours for twelve sprays of Pompons, three flowers to a spray, with foliage as cut from the plant, with even-sized blooms of leading varieties.

Plants.—For the best group of Chrysanthemums arranged in a space not exceeding 30 square feet there were five exhibitors, all staging in the usual bank style. Nearly all had good blooms, but in some instances a great want of finish in arrangement was perceptible, too much of the bare stems and pots being visible; with a little more attention to this the groups would be greatly improved. Mr. Gale had much the best arrangement, Mr. Hawkins second. For six specimens, the diameter to be not more than 3 feet, there were four entries, Mr. Gale easily leading with freely trained and flowered examples of Mrs. G. Rundle, Madame Bertier Rendatler, and Lady Selborne; Mr. J. Groom, Gosport, second. Mr. Gale was easily first for six Pompons, freely flowered.

Apples and Pears in four dishes of each were well shown by Mr. J. Long, gardener; Mr. Walter Bunney and Mr. Hawkins both staging well in their respective sections. The latter exhibitor staged the best black Grapes—Alicante, while Mrs. Groom had the best white in two bunches. The competition in the vegetable classes was keen, Mr. Hawkins winning for nine varieties.

HAVANT.

THE Havant Chrysanthemum Society held its sixth annual Show at the Town Hall, Havant, on the 1st and 2nd inst. This Show is not one of the largest of its kind, but the products shown—whether flowers, fruit, or vegetables—are of high quality throughout. The "Havant" is one of those local Societies started and managed by a few kindred spirits within the township, and the amount of enthusiasm and hearty goodwill among its members gives one an insight into the benefits derived by such associations, apart from the mere growing of Chrysanthemums.

The exhibits this year were quite up to the usual good quality. In the vegetable classes Mr. N. F. Fuller, gardener to Sir J. Clarke Jervoise, Bart., Idsworth Park, maintained his reputation as a highly successful cultivator in the kitchen garden; Mr. C. Penfold, Mr. J. Garnett, gardener to Major Reeves, and Mr. Kinshott, gardener to Mrs. Hodgkinson, also showing well in these classes. Grapes and other fruits were of excellent quality throughout, and brought strong competition, principally by the same exhibitors in the Chrysanthemum classes, showing that "mums" do not occupy all a gardener's time.

This year there was only one class for plants, and that for a group. Three splendid masses were put up, the quality of the blooms being in many instances equal to the best of the cut flower classes. The prizes were awarded to Mr. W. Roberts, gardener to E. R. Longcroft, Esq.; Mr. W. Moseley, gardener to J. Taplin, Esq.; and Mr. Agate, florist, Havant, in the order named. *Cut Flowers.*—In the principal class for twenty-four blooms, twelve incurved twelve Japanese, the first prize fell to Mr. Penfold, gardener to Sir T. Fitzwygram, Bart., M.P., who staged very fine blooms of Incurved.—Empress of India, Refulgens (rarely seen so fine), Lord Alcester, Golden Empress of India, Lord Wolseley, Mrs. Heale, Violet Tomlin (good), Jeanne d'Arc, Miss M. A. Haggis, Princess of Wales, Mrs. W. Shipman, and Prince Alfred. Japanese.—Pelican (very fine), Madame C. Audiguier, Carew Underwood, Baronne de Prailley, M. J. Pigny, Edwin Molyneux, Condor, Val d'Andorre, Ralph Brocklebank, Florence Percy, Bernard, and Sunflower (the latter magnificent). The second prize went to Mr. A. Payne, gardener to Mrs. Ernald Smith; third, Mr. Woodfine, gardener to C. P. Boyd, Esq.; fourth, Mr. Fuller, who staged the best bloom of Avalanche, an exceedingly fine example. For eighteen cut blooms, first, Mr. W. Roberts; second, Mr. J. Agate; third, Mr. W. Moseley. The winners of other classes were as follows:—For twelve Japanese, Messrs. Penfold, Woodfine, and Payne; for twelve incurved, Messrs. Penfold, Payne, Roberts, and Agate; for twelve Anemones, Messrs. Penfold, Payne, and Fuller; for twelve reflexed, Messrs. Woodfine, Roberts, and Penfold; for twelve Japanese Anemones, Messrs. Penfold, Fuller, and Agate; for

twelve new varieties, Messrs. Agate, Penfold, and Fuller; for twelve Pompons, Messrs. Roberts, Agate, and Moseley.

In the amateur classes Mr. J. Horril, master of Havant Union, Mr. R. Sainthill, and Mr. H. M. Green, all showed with much credit in several classes. There was also a class for hand bouquets, but the exhibits were wanting in taste and badly arranged.—D.

FRUIT FORCING.

FIGS.—Early Forced Trees in Pots.—If these have been placed in the open air they should be taken under cover to protect them from the cold autumn rains. It is presumed that the trees have been top-dressed and repotted, or had the drainage rectified, as advised in a former calendar. The trees should be placed in a rather dry well-ventilated house. Any thinning or shortening crowded attenuated growths must be attended to, and the trees dressed with an insecticide; 8 ozs. of soft-soap to a gallon of water may be used for washing the trees, using a somewhat stiff brush, especially if scale has been present, following with the same to which sulphur has been added to bring it to the consistency of cream, being careful not to damage the points of the shoots and the embryo fruit. A dish of forced Figs early in the season is now considered a daily necessity in large establishments, and it is not by any means difficult to obtain, but a well-ventilated house is necessary, with the command of plenty of heat, having pits containing fermenting materials to afford bottom heat to stimulate the roots. The Figs in pots require abundance of liquid manure when growing, the trees being most prolific under limited root space. One of the great advantages of Fig culture in pots is the number of varieties that may be grown in a house of moderate dimensions, which, if forced early, come in at a time when the dessert is not too varied. Brown Turkey is unquestionably the best Fig for general purposes, and the best white is White Mar-silles. The following are also well suited for forcing and pot culture: Osborne's Prolific, Early Violet, Black Ischia, Brown Ischia, Violette de Bordeaux, Negro Largo, Angelique, White Ischia, Col di Signora Bianco, and Royal Vineyard.

Early Forced Planted Out Trees.—These should now be untied from the trellis and pruned. Those with the roots restricted to small borders will require the shoots thinned where too crowded, but those not having the roots restricted will need a hard pruning at the upper part of the trellis, cutting back those shoots that have reached the limit where the succeeding shoots are to start. Remove any elongated spurs, reserving such as are short jointed and fruitful. The house should then be thoroughly cleansed, washing the woodwork with scalding water, and the walls afterwards with quicklime and sulphur. Wash the trees with soapy water, and afterwards dress with an insecticide. Then secure the trees to the trellis, allowing room for the growth of the branches, forking the surface of the border slightly, removing the loose material, and apply a top-dressing of short partially decayed manure, about 3 inches thick, giving a good watering. Ventilate freely at all times, except when frost prevails.

Succession Houses.—Prune and cleanse the trees without delay, especially where insects are present. Complete any root-pruning and lifting, remembering that Figs with the roots restricted or confined to limited areas are more manageable and fruitful than with an unlimited root area. Any unfruitful trees should be rather severely root-pruned, and the roots restricted to moderate-sized borders, depending more upon active feeders near the surface encouraged by mulching than a large extension of roots.

VINES.—Early Forced.—Those Vines for affording ripe Grapes in April must now be started, whether in pots or planted out. Bottom heat in neither case is indispensable, though in all forcing operations it hastens growth considerably; therefore place fermenting materials in the pit, in which case those in pots are stood on pedestals of loose bricks, being careful not to allow the heat about the pots to exceed 70° to 75°. Suspend the canes in a horizontal position over the fermenting material to insure a regular break. Syringe three times a day, keeping every part of the house moist by sprinkling in bright weather. Vines started at this season require a higher temperature to excite the buds than those started later. A temperature of 50° to 55° at night and 60° to 65° by day will not be too much to start with. Those planted out should have the border inside thoroughly soaked with water or liquid manure, preferably at 90°. The border or floor of the house should, if convenient, be covered 2 feet deep with leaves and stable litter in a state of fermentation, occasionally turning the material, as the ammonia given out along with the moisture is very beneficial. The outside borders must be covered, if fermenting materials are not obtainable, with a good thickness of leaves, with tarpaulin, shutters, or lights to throw off rain or snow.

Houses for Starting in December.—Complete the pruning, as it promotes rest. Two buds are ample for affording useful bunches, but Vines that do not afford bunches as large or so freely as desired should be

allowed more—four to six, according to their vigour, yet with the wood stout and short jointed the close pruning will afford the best results, as what is gained in size of bunch is lost in size of berry, compactness of bunch, and good finish. A useful bunch of well coloured thoroughly ripened Grapes is always appreciated. Dress the Vines, cleanse the house, having all in good order ready for a start at the proper time.

CUCUMBERS.—Allow a night temperature of 70° in mild weather, 5° or 10° less in severe weather, and maintain a temperature of 70° to 75° by day artificially, advancing to 80° and 85° with sun heat. Admit a little air at the top of the house whenever the weather is favourable, but it must be done without lowering the temperature, as it is better to shut off the top heat for an hour or two when the sun is powerful than to admit air when the winds are sharp and cold. Moderate ventilation is, however, beneficial in carrying off steam or accumulated moisture. The syringe may be laid aside except for damping the paths and walls in the morning and afternoon in warm bright weather, keeping the evaporation troughs filled with liquid manure. The water or liquid manure given to the roots must be of the same temperature as the house, as also must the soil that is added to the beds.

The autumn fruiteders being now in full bearing must not be over-cropped, therefore remove the fruit as soon as it attains a fair size, and all deformed fruits when seen. Examine the plants at least once a week for the removal of bad leaves, stopping or cutting away superfluous growths.

Let the winter fruiteders advance well up the trellis before stopping them, training the side growths evenly, and not more closely than to allow of the foliage being exposed to light. Stop at a few joints of growth, or one or two joints beyond the show of fruit. Allow few or no male blossoms or tendrils, removing them as fast as they appear, and add fresh warmed soil as often as the roots have fairly covered the surface of the bed.

THE BEE-KEEPER

WEAK STOCKS AND HOW TO TREAT THEM.

THERE are at the present time not a few bee-keepers who, either owing to inexperience or want of care, have stock hives which, even if they survive the winter, will, unless extra precautions are taken to assist them, fail to give satisfaction to their owners. In order to secure early swarms—and early swarms mean increased profit—all stocks in autumn should be made strong in bees and well supplied with food, so that however inclement the spring may be there will be no risk of starvation. This is very necessary, for it is well known amongst bee-keepers of experience that bees are provident insects, and unless they see stores in sufficiency within their reach, will decline to add to the number of consumers by rearing brood. Some time ago I gave my reasons for condemning the spreading of brood, so strongly advocated by some bee-keepers who have found it answer. In my experience nothing is necessary to ensure early swarms but a proper judicious autumn preparation. It is, however, now too late for those who have not already done so to remedy the evil which must follow from their negligence if means are not taken, as far as possible to alleviate the mischief. I am thinking more particularly of stocks which have store sufficient to last until the end of February or the beginning of March. In passing it may be well to remark that if doubt exists as to there being a sufficiency of food to last until that time candy should be supplied at once, and a fresh supply given as soon as the first is consumed.

With respect to stocks which are rather weak in bees but have honey enough to last till March, it appears to me that it is wiser and better to act in a somewhat different manner. Suppose, then, we have a stock in March whose food supply is deficient, 5 or 6 lbs. of good beet sugar syrup should at once be given as rapidly as the bees will take it. If then the weather is not very cold give a few ounces of syrup every day until the season is so far advanced that natural supplies take the place of artificial. It has never seemed to be necessary to use any of the clever inventions so freely recommended for limiting the supply of syrup or allowing the bees to take only very little at once. For this purpose no feeder is, as far as I can see, in any way superior to a cover or bottle of small size filled or partially so each day, covered with net or muslin, and inserted on a piece of perforated zinc placed permanently on the top of the hive. This bottle filled each day is quite a sufficient stimulant for any,

stock, but when once this feeding has been commenced it must not cease, even for a few days, or the result will probably be to undo all the benefit which weeks of care have conferred upon the stock. In using a bottle feeder there is some little care requisite in order to obtain the best results, and it may not be lost labour to explain somewhat in detail the method which appears to be the best. On the hive, then, which it is intended to feed a piece of perforated zinc should be placed large enough to take the place of the cover previously in use on this zinc; a piece 4 inches square is a good size, and can be used either on a straw or wooden hive. Several pieces of thick carpet should then be placed on, each one having a hole in it just large enough for the insertion of the neck of the bottle; the whole should be covered when the feeder is in position with warm material in order to keep all snug and prevent the loss of heat. Two bottles for each hive much facilitate the operation, the one ready filled to take the place of the one removed when emptied by the bees.

It is hardly necessary to add that the greatest care must be taken not to spill the syrup, which for spring feeding may be of a rather poorer quality than that used in autumn, because in spring more water is required for the brood, and if a larger proportion of water is used in the syrup the bees are not compelled to go abroad for it when the weather is so bad as to be very destructive to them. It must be understood that stimulative feeding is only recommended here in order to repair previous neglect. If a hive has been properly prepared, and no accident happens to prevent it, either by the loss or debility of the queen, a swarm will certainly issue in the early part of May.

But it may be said there is danger attendant upon this feeding, and in this respect it is little better than spreading brood. That there is some danger in thus feeding a stock in early spring cannot be denied, because the bees are thereby incited to fly on days and in weather when stocks left to themselves are quiet, but it cannot compare with brood-spreading for danger. In order to spread brood the hive must be opened and the cluster disturbed, heat lost, and the brood nest artificially enlarged, and unless the operator is a man of experience often enlarged so greatly as to prevent the bees on cold frosty nights, which occur even in late spring, from keeping up heat sufficient to hatch out all the eggs deposited. Stimulative feeding does no doubt induce the queen to lay more freely than she otherwise would do, but there is no loss of heat by opening the hive, dividing the cluster, and disturbing the bees. If a stock is strong and has a good store of honey it should be left undisturbed, and the very fact that so much more time has to be expended on a weak stock in order to bring it up to swarming point as early as a stronger and better provided hive shows how great a saving there is in having all the stocks strong enough to cause no anxiety or fear.

Stimulative feeding in spring is sometimes a necessary evil. Judiciously done no harm accrues from its use, but care is essential in this as in every other operation not to carry the practice to an extreme. In spring every cell filled with honey not required for use is a bee less, so that it is evident that to give too much defeats the object we have in view. A hive cannot be too warm in spring, so that great care should be taken to wrap up any feeder which may be used as warmly as possible in order to retain the heat, without which no brood can be raised. In cases of this description it is well for a bee-keeper who doubts the efficiency of this practice to try half his stocks assisted as explained above, the other half left to their own devices, but supplied, of course, as early as the weather will allow with syrup enough to last until the end of April or beginning of May. In trials such as these the queen of one stock may and is sure to be superior to the queen of another, but still a fair idea of the merit of the system may be gained by a careful watching over the results following from its adoption, and its value or worthlessness proved by all who have the good fortune to be bee-keepers, and who hope some day to be bee-masters.—FELIX.

“All correspondence should be directed either to “THE EDITOR” or to “THE PUBLISHER.” Letters addressed to Dr. Hogg or members of the staff often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post, and we do not undertake to return rejected communications.

TO CORRESPONDENTS.

In consequence of the extraordinary pressure that will be experienced during the Chrysanthemum season questions cannot be answered with the usual promptitude, and especially those arriving after Saturday. See notice below relative to the naming of fruit.

Taking a Business (B.).—We would not advise you to take a business on so small a capital unless you have had full experience in the matter. The majority fail from starting with insufficient capital, but in any case very much must depend upon a man's energy and industry.

Hyacinths in Glasses (E. M.).—We have heard of a few drops of ammonia being added to the water, but have not tried it, and the finest of spikes are grown in soft water with a few pieces of charcoal placed in to keep it pure. We attach far more importance to sound solid bulbs than to any manurial additions to the water.

Pear Tree Decaying (An Old Subscriber).—The tree is probably worn out, or the roots are either in cold wet soil or in a dry poor medium. Trees cannot grow healthily if the roots do not work freely in soil from which they can gather sustenance of the proper kind for fruitful growth. You do not say a word about the soil, therefore we cannot tell what treatment might improve it and do the tree good.

Fruit Trees for Chalk Soil (E. A.).—The chalk being overlaid by a foot or more of good loam is a suitable one for most varieties of Apples and Pears, those named in answer to “J. C. D.” being suitable. A chalky soil is peculiarly suited to Plums, some of the best of which are Jefferson, Green Gage, Oullins Golden, Kirke's Transparent Gage, and Coe's Golden Drop; and for culinary purposes Early Rivers, Morocco, Victoria, Magnum Bonum, Pond's Seedling, and Nectarine Plum.

Selection of Apples and Pears for Succession (J. C. D.).—Dessert Apples:—Irish Peach, Kerry Pippin, King of the Pippins, Cox's Orange Pippin, Ross Nonpareil, Adam's Pearmain, Rosemary Russet, Reinette de Canada, Ribston Pippin, Court Pendu Plat, Lord Burghley, and Sturmer Pippin. Kitchen Apples:—Keswick Codlin, Lord Suffield, Stirling Castle, Golden Noble, Cellini, Cox's Pomona, Ecklinville, Bramley's Seedling, Lane's Prince Albert, Kentish Fillbasket, Winter Greening, and Norfolk Stone Pippin. Dessert Pears:—Jargonelle, Williams' Bon Chrétien, Beurré d'Amanlis, Flemish Beauty, Beurré Superfin, Louise Bonne de Jersey, Doyenné du Comice, Marie Louise, Pitmaston Duchess, Winter Nelis, Glou Morceau, and Josephine de Malines.

Evergreen Flowering and Berry-bearing Shrubs (Idem).—Arbutus Unedo Croomi, Aucuba japonica limbata, A. longifolia, and A. maculata, but to have these produce berries it is necessary to have the male variety, A. japonica maculata; Berberis Darwini, B. stenophylla, Buddlea globosa, Cotoneaster microphylla, Daphne Fioniana, Escallonia macrantha, Garrya elliptica; Hollies, both green-leaved and variegated, in great variety; Ligustrum sinense nanum, Olearia Haasti, Rhampholepis japonica, Skimmia japonica, Ulex europæa flore pleno, Veronica Traversi, and Viburnum Tinus. In suitable soil there are the finest of flowering evergreen Rhododendrons in endless variety.

Name of Apricot (Young Hand).—It is almost impossible to correctly name a variety of Apricot from leaves only. We have compared those sent with the leaves on the trees forming a fairly large collection, and in all probability if you order the Royal you will get what you require. The following description of this variety taken from Dr. Hogg's “Fruit Manual,” may serve as a clue:—“Royal.—Large, oval, and slightly compressed; skin, dull yellow, tinged with red where exposed; suture shallow; flesh, pale orange, firm, juicy, and vinous, separating from stone; stone, large and oval, impervious; kernel, bitter. An excellent Apricot, and little inferior to the Moorpark. Ripe in the beginning of August.”

Name of Beetle Grub (J. T.).—There were grubs enclosed, but not a beetle also, as stated by you, which must therefore have in some way escaped, but it is not likely to be the species into which the grubs develop afterwards. They are those of the destructive weevil, *Otiorynchus sulcatus*, and occur from August to March at the roots of plants. Probably they feed throughout the winter, as cold appears to have no effect upon them. Soot and lime have been sometimes found to kill this grub, also a weak solution of paraffin combine with soap, but it is not easy to remove it without injuring the plants. In soil suspected to contain this grub, where the plants have been removed, its extirpation may be accomplished by working in some fresh gaslime, previously combined with an equal quantity of dry earth.

Seyphanthus volubilis (S. T. W.).—*Grammatocarpus volubilis*, better known under the name of *Seyphanthus elegans*, is a native of Chili, whence it was introduced to this country about the year 1824, but from inattention to the collecting of seeds was lost to cultivation, appearing again among more recent introductions. It is a hardy annual, having a very slender twining stem, which is hard and wiry, covered with small stiff hairs bent downwards, making it rough to the touch, but entirely devoid of the stinging properties of its near ally the *Loasa*. The leaves, which are opposite, are pinnatifid, with fringed margins. The flowers are large, cup-shaped, and of a beautiful lively yellow tint, being sessile and terminal when the buds first appear, but the young shoots are generally produced on each side, so that when full expanded it is between two branches or forks. Planted against a south wall with a few twigs to cling to it has a very pleasing effect, growing from 8 to 10 feet high, and is well adapted for covering old or unsightly walls. It is also well adapted for covering trellis-work in the flower or pleasure garden, and is unequalled in the form of a screen, having also the advantage of giving variety to those generally grown.

Indigoferas (J. H. M.).—Several species are grown, such as *I. decora*, *I. floribunda*, and *I. incana*, which are evergreen shrubs, with pea-shaped flowers, of a pink or rosy purple colour. They are of free growth, and require the wood well ripened to ensure profuse flowering. Prune in February or March, when the plants are beginning to grow, cutting them in rather closely, or in case of old plants spur the shoots in to two or three eyes of their base. Young plants will need to have the shoots left longer, and if in a cool, airy part of the house they will break naturally and strongly. When the young shoots are an inch long turn the plants out of the pots, remove most of the old soil—all that comes away without destroying the roots—put in the same size of pot or a little larger, and place in a close pit, shading from bright sun until the potting is recovered from, then expose to light and air, syringing with water morning and evening up to flowering time to keep down red spider. When the roots are slightly matted around the sides of the pot shift into a pot 2 to 4 inches larger in diameter, providing good drainage. Water abundantly when growing and flowering, afterwards expose fully to light and air, and in winter keep the soil dry, not, however, so as to cause the wood to shrivel or leaves to fall prematurely. Equal parts of sandy peat and fibrous loam, a little leaf soil or old dry cowdung and silver sand, with a like quantity of pieces of charcoal, form a suitable compost. They attain a height of 3 to 4 feet, and are best trained as bushes.

Lilacs for Forcing (W. W.).—If you require a supply of blooms for cutting and plants suitable for decoration from early in the season until the flowers are plentiful outside, lifting plants from shrubby borders and returning them to these quarters again after they have flowered will in time end in disappointment. The best variety for forcing and yielding a supply of bloom, either white or its natural colour, is Charles X. In order to be successful two batches of plants should be grown, so that they can be forced alternately into bloom. Those forced last winter and spring and retained in pots will not have made growth sufficiently strong to flower again this year. These plants should now be cut hard back, leaving only one eye of the young wood for the growths to start from another year. They should be turned out of their pots, the balls partially reduced, and then placed in 7 or 8-inch pots according to their size and strength. The pots used should be fairly drained, and the soil—good fibry loam and one-seventh of manure—pressed firmly into them, and the pots plunged outside. The rim of the pots should be completely covered either in ashes or with soil in an open sunny position. When subject to this treatment very rarely do the plants give any labour in watering during the summer months, but make short, stiff, sturdy growths, varying from 9 inches to 1 foot in length, which by autumn are studded with large prominent flower buds. The plants before the end of the season are sure to root over the surface of their pots, but these can be cut off without the slightest injury to the plants. If this variety is planted out it usually grows too strongly to ripen its wood sufficiently.

Names of Plants.—We only undertake to name species of plants, not varieties that have originated from seed and termed florists' flowers. Flowering specimens are necessary of flowering plants, and Fern fronds should bear spores. Specimens should arrive in a fresh state in firm boxes. Slightly damp moss, soft green grass or leaves form the best packing, dry wool the worst. Not more than six specimens can be named at once, and the numbers should be visible without untying the ligatures, it being often difficult to separate them when the paper is damp. (W. R.).—1, *Primula floribunda*; 2, *Primula poeuliformis*; 3, *Helleborus niger maximus*. (S. T.).—1, *Acacia platyptera*; 2, *Lueulia gratissima*. 3, *Azalea linearis*; 4, *Rhododendron javanicum*; 5, *Adiantum pedatum*.

Names of Fruits.—The names and addresses of senders of fruit to be named must in all cases be enclosed with the specimens, whether letters referring to the fruit are sent by post or not. The names are not necessarily required for publication, initials sufficing for that. Only six specimens can be named at once, and any beyond that number cannot be preserved. (*Shillingstone*).—Cox's Orange Pippin. (*H. F.*).—1, Hanwell Sourcing; 2 and 3, Tower of Glamis; 4, Dutch Mignonne; 5, Betty Geeson; 6, London Pippin, highly coloured. (*W. M.*).—1, Cox's Orange Pippin; 3, Beauty of Kent; 4, Cellini; 5, Golden Pearmain; the others not recognisable. (*F. A.*).—1, Frogmore Prolific; 2, King of the Pippins; 3, Cellini; 4, Ribston Pippin; 5, Flower of Kent. (*W. S.*).—The Pear is Laure de Glymes; the Apple is not Alfriston, and we are not sure what it is; it differs from all in the Chiswick collection, and is very handsome. Do you think it is of local origin? (*F. B. R.*).—1, Lord Grosvenor; 2, Charlotte de Brouwer; 3, Huyshes's Victoria; 4, Beurre Diel. (*F. G.*).—1, Lemon Pippin; 2, Hollandbury; 3, not known; 4, Beauty of Kent; 5, Frogmore Prolific; 6, Calville St. Sauveur. Several boxes of fruit arrived without the names and addresses of the senders in them, and the letters received by post do not aid us in the identification of the consignments, therefore the fruits cannot be named. Our instructions above are clear on the point of sending fruit for identification.

* * In consequence of Dr. Hogg's absence from London fruit sent to this office cannot be named by him during the present month.

COVENT GARDEN MARKET.—NOVEMBER 6TH.

MARKET very quiet, with good supplies. Prices unaltered.

THE FLOCK IN WINTER.

SHEEP folding in winter is so important that we turn from further details of ewe management for the moment to the work of folding crones and hoggets. Crones, we may explain, are old ewes that, having ceased to be useful for breeding, were withdrawn from the flock at weaning time last June. They may then be purchased to advantage for folding if due care is taken to secure sound animals in fair healthy condition. This is not an easy matter, for crones are frequently sent to market in a terribly emaciated condition, and hardly a flock can be seen without a few worthless ewes, upon which debility or disease have so strong a hold that profit is out of the question, and loss is almost a certainty. The purchase of such "wasters" can easily be avoided by the offer of a fair price for sound animals only, all others to be withdrawn. A little firmness and tact must be brought to bear upon this transaction, for cattle dealers almost invariably make up flocks for sale, enough really fine sheep being put in to attract the eye and take off attention from the inferior ones, which are certain to be present in considerable numbers. If there are enough sound healthy sheep to render an offer desirable they are generally to be had by giving a trifle more per head for the privilege of selection.

Preference is given to crones for folding because they enrich the soil more thoroughly than younger sheep, but we do not mind whether it is hoggets or crones so that they are healthy. Old neglected pasture may be reclaimed by a clearance of all tall-growing weeds, such as Thistles, Nettles, Docks, Broom, Ononis, Gorse, and Brambles, and following with folds, using a hurdle to a sheep, which determines the size of the fold, and turning into a new fold every twenty-four or forty-eight hours, according to weather and condition of the pasture. The folding may be repeated advantageously with certain modifications every winter, and there will be both vigorous growth and better herbage—many of the smaller weeds will disappear, to be replaced by really useful growth. The manner in which the sheep are fed in the folds is very much a question of expediency. A mixed dietary is undoubtedly best, and it may consist of crushed corn from a half to a pound mixed with hay chaff in the troughs, pea or oat straw in racks, and sliced roots also in the troughs at the rate of about 20 lbs. daily. Oats, Barley, Wheat, Peas, and Beans are all good for sheep, and there is very little difference in the results from the use of any particular sort of corn. Last winter large quantities of Barley were used for hoggets simply because the grain was discoloured and the price so low that it answered better to use it for feeding purposes at home than to dispose of it to the maltsters. This season the Barley trade is altogether better, and it will answer better to use Oats and pulse for the sheep. The Woburn trials prove beyond a doubt that Wheat may be used to advantage for sheep, and it would be well to turn inferior samples to account for the purpose; but fine, bold, dry samples will continue to find a profitable market among the millers, no matter how prices may fluctuate.

Silage on many farms will commend itself for our purpose as a valuable addition to the dietary either used alone or mixed with chopped straw. The use of mixed food is so beneficial that every wholesome change is desirable. A change of quarters, too, is often productive of good, and it can often be managed for the sheep by having folds on Turnips as well as on pasture at the same time. Then if the weather is dry and open good progress may be made among the Turnips; if wet, then the sheep may be withdrawn to pasture. If kept persistently in Turnip folds, in very wet weather,

even hoggets do not make satisfactory progress; foot rot is apt to spread too, and that always lowers the condition.

The feeding of hoggets in folds also depends upon when they are required to go out for sale—forward hoggets having a full quantity of corn, and backward hoggets a lesser quantity of corn, with more of other food. The use of linseed or compound cakes for hoggets or crones is entirely an open question. If corn is cheapest, and it answers as well, of course it will have preference, but under certain local conditions, such as contiguity to a cake mill, and avoidance of cost of carriage and middlemen's profits, cake may be used. But for farmers generally, home grown corn, or corn purchased at low wholesale rates, answers best. Whatever food is used it must be sweet, fresh, and wholesome, only enough being used each time for the sheep to clear up, with, perhaps, the exception of straw in racks, to which they should always have access in winter folds.

(To be continued.)

WORK ON THE HOME FARM.

Very little progress has been made with the Wheat sowing, except on light land farms, where a few hours' fine weather is all that is required to render the surface dry enough for the drill. Glad indeed have we reason to be that we began sowing our heavy land early in September, for we have now an excellent full plant. But without such promptitude and timely sowing we might have now to wait indefinitely. This statement affords no help or comfort to those heavy land farmers who have fallen behind with their work, but we mention it simply to apply a useful lesson for the future guidance of our readers.

The incessant rain has done much more harm than retard Wheat sowing, for it has spoilt thousands of pounds worth of Clover seed. This at best is a speculative crop, but the risk sinks to a minimum if the first growth of the layer is fed off by sheep, and then the second growth comes to maturity soon enough for the seed to ripen before the weather becomes much broken, and the seed is saved. That is precisely what has happened this year, and it is where the first crop was mown for stover that the second growth reserved for seed has been spoilt. We regret this all the more because the seed was so abundant, especially in the later heads. We deplore the serious loss greatly, although it is probably confined to the seed-growing district of East Anglia. We know a farmer who managed to save half the crop, when down came the rain day after day, so that the remainder had to be carted off the land to the cattle yards. Another declares his loss amounts to full £300, which sum would have been all to the good at the end of the year.

A severe case of swine fever has been traced to its source, and it was found that it had been spread from farm to farm by sows driven from the one farm where the fever originated. No doubt the filthy condition in which swine are kept so generally renders them predisposed to contagion, and we can only repeat previous advice to keep pigs in as cleanly a condition as all other animals. All compact plump porkers may be disposed of now quickly as Londoners, but those with larger frames answer best if kept for "jointers." None of them should be fed carclessly, but each class of pig should be pushed on and ripened for market as quickly as possible with home grown corn.

METEOROLOGICAL OBSERVATIONS.

CAMDEN SQUARE, LONDON.

REMARKS.

- 27th.—Very wet from 4 A.M. to 2 P.M., and dull and damp after.
 28th.—Damp and foggy early, and occasional spots of rain throughout the day.
 29th.—Fog early; dull day, with occasional spots of rain.
 30th.—Bright pleasant day, rain at night.
 31st.—Rain in small hours; bright pleasant day.
 1st.—Wet from 7 to 10 A.M., then bright and mild.
 2nd.—Bright and fine.

Although rain was recorded on six days, much of it fell at night, and there were four pleasant sunny days. Temperature about the average, with little range.—G. J. SIMONS

KEEPING GRAPES.

THE most critical period for keeping Grapes on Vines that have their roots outside in unprotected borders, is from the time the foliage commences to assume an autumnal appearance until it falls, as the berries are more liable to decay at this stage than at any other. The main evils that the cultivator has to contend against are late ripening, overcrowding of the berries, large shouldered bunches, and an injudicious use of fire heat while the Grapes hang on the Vines.

We are convinced that Grapes expected to keep well without the loss of a berry should be thoroughly ripe by the middle of September at the latest. It is important that the Vines have rather a long period of growth; they should be started early in the season and assisted by heat, so that when colouring commences they can be allowed abundance of time in which to ripen. During August there is generally plenty of sunshine, and a moderately warm, dry, and airy atmosphere can be readily maintained. Warmth and ventilation at night in addition are the conditions under which the Grapes will develop superior flavour to those that ripened in a high temperature and close moist atmosphere six weeks or two months later in the year.

Attention is needed at the time of thinning or before the stoning commences. It may surprise some when we say that we go over our late Grapes three times before the process of thinning is completed. First, all small berries are removed, and sufficient to prevent crowding until the remainder have commenced swelling freely. The second time does not take long, when all inside berries are removed, and as nearly as we can judge the process is completed. During this second thinning shoulders that are liable to hang or press in any way against the remainder of the bunch when bottled are removed or reduced as required. Where any crowding results from one portion of the bunch pressing against the other the berries are most liable to decay. The same weight of Grapes can be taken from the Vines whether the bunches are large or small, and from careful observations during the past thirteen years we have found that bunches ranging from 1 lb. to 1½ lb. keep better than those of a larger size. Larger bunches can be kept equally well if they are tapering, long instead of wide, where the inside berries can be removed, and there is no pressure from above. Bunches that are short, thick, and heavy at the top are avoided as much as possible.

The third time the bunches are examined is after the berries are stoned. It can then be determined if any are likely to press unduly against others. In some bunches not a single berry may need removing, whilst in others the berries may display signs of swelling to an extra size when it may be necessary to remove one here and there. Whether thinning is done at one or three times matters very little provided the Grapes have room to swell and when ripe are not crowded. Bunches in which the berries are jammed together will not keep satisfactorily. What use are bunches 4 or 5 lbs. in weight if there is a doubt about keeping them, or if in the end they are much reduced in weight by the removal of decayed berries? It is much wiser to have two or three bunches on the Vines that will keep instead of one. Large bunches certainly take the eye, and are something to boast about, but for all practical purposes those of a smaller size are much more useful, and more suitable for market purposes. It is not too late even now to

improve under-thinned bunches. It is better to remove a few berries at once than allow them to remain and eventually decay and probably disfigure the whole bunch. The removal of one berry at the present time may prevent the loss of two or three later on, for if one turns mouldy the adjoining two or three are almost certain to decay as well, thus causing a considerable vacancy in the bunch.

We have found it a good practice to admit more light to the Grapes that have to be kept until the spring than is necessary for those that are used from the Vines by the close of November. When the Grapes are coloured we commence removing the sub-laterals a few at a time until all can be cut away without fear of the main buds bursting again into growth. By the end of September, or early in the following month, only the chief leaves along the laterals remain. Not only is light admitted to the Grapes but to the wood to further ripen and solidify it. It is also a fact that Grapes keep better on wood that is firm and well matured than they do on strong, soft, pithy, unripe wood.

Early ripening of the Grapes not only proves an advantage in keeping the fruit, but it is the most economical as regards the consumption of fuel, a matter of no small moment at the present time. Leaving out the question of economy, however, the Vines can be subjected to cool treatment much earlier than would otherwise be the case. This tends largely to reduce to a minimum the risk of losing berries during the period when the foliage commences to decay. The atmosphere externally is often heavily charged with moisture, and the continuance of fire heat only adds to the evil. When fire heat is used at this stage it is difficult to keep the berries from being covered with moisture, a condition that is almost certain to end in large numbers decaying. If the ventilators are closed and fire heat used when the atmosphere is moist outside, or heat and ventilation employed together, the atmosphere about the Grapes is very similar in both cases as far as a deposit on the berries is concerned. The best course is to use as little fire heat as possible after the Vines have once been gradually brought to cool treatment, and then principally on very fine days when liberal ventilation can be given. A slight deposit on the berries appears, however, to do no harm when the temperature is low, provided it be quickly evaporated, but when the temperature is higher and moisture settles upon the berries decay quickly commences. Heat and the condition of the atmosphere not only aid rapid decomposition, which is much quicker in late than early ripened Grapes, but it tends largely to shrivel the berries. Alnwick Seedling, for example, cannot endure fire heat after it is ripe. The berries quickly commence shrivelling where fire heat is used daily and the orthodox ventilation provided until the Grapes are cut and bottled, or the foliage has fallen. We have watched this variety closely during the past two years, and find that it keeps plump much longer than when we used more fire heat to our late Grapes.

The greatest difficulty after the Grapes are ready for removal from the Vines, in most gardens, is to find a suitable place in which to store them. Fruit rooms are often selected, and large numbers of these are anything but suitable. A room, whether in a northern or southern position, that is naturally dry, where a good circulation of air can be maintained will do very well. A free circulation of air is important, and where it can be secured all means of heating can be dispensed with. When we used the ordinary fireplace in our room, or the two gas jets provided for maintaining a uniform temperature, the Grapes did not keep nearly so well as they have since their use was discontinued. Warmth during severe weather resulted in the berries being covered with dew in the morning, and for days together we had the greatest difficulty in dispelling it, with the result that the berries decayed rapidly. When the fire was used a circulation of air was cut off, and the moment the door or window was opened and air admitted the Grapes were almost white with the moisture

deposited upon them. When ordinary wine bottles are filled with water and suspended in a cool room they will need no attention in refilling, except the few in which those are placed that have very short laterals. These should all be arranged together, so that they can be looked over occasionally to keep the stems in the water. No charcoal need be placed in the bottles, this practice is a waste of time, the neck of the bottle need not be stopped with clay or any other material, and the ends of the shoot need not be sealed or even charred. These are superfluities, and should not be taken into consideration, all that is required is to cut the bunches from the Vines with the laterals attached and place them in the bottles of water. If the room is ventilated liberally on all favourable occasions few berries will be lost if the Grapes have been well ripened and liberally thinned. When they are kept in a cool room they retain their bloom and colour to the last, and their flavour as far as we have been able to judge is not impaired in the least. Last April our Alicantes in appearance and flavour were as good as when they were cut from the Vines. When fire heat was used after bottling they gradually lost their colour and flavour in a marked degree.

The Grapes from late Vines where the fruit is intended for use during the months of March, April and later, may be cut from the middle to the end of December. The fruit intended for use during the months of December, January and February may be removed, and the Vines given a chance to rest directly the foliage has fallen naturally.—WM. BARDNEY.

AUTUMN WORK AMONGST GLADIOLI.

THERE are three subjects which will much interest the growers of Gladioli at this season of the year:—1, The lifting and storing of corms; 2, the preparation of the ground for next spring planting; and 3, the adding to the collection of newer sorts which have proved valuable additions, and on each of these subjects I may say something from my own experience of thirty years or more of their culture. Of course, I am alluding to the hybrids of *gandavensis*. I have grown for some years some of Lemoine's hybrids of *purpureo-auratus*, which are increasing in size and beauty every year, a white one having been obtained in Venus de Milo. I have found them in this part of England (Kent) to be perfectly hardy; and it should be borne in mind that although we are in the Garden of England, and so far to the south, yet we are subject to very sharp frosts. My corms have been left in the ground for six years, and have not only not suffered but largely increased. This will probably satisfy your correspondent, "W. J. M.;" in fact, I cannot suppose that there is any part of Ireland where they would not be perfectly hardy. Mr. W. E. Gumbleton grows them in Cork to great perfection, and with him they are perfectly hardy. True that is a favoured locality, but I should think it is equally true with other parts of the country. The hybrids of *nanus* I cultivate in pots, so that I have now to do with those of *gandavensis* only.

This season is rather a puzzling one. What we want in October is what they generally have at Fontainebleau, a dry and sunny month; instead of that we have had up to October 28th more than seven inches of rain; the ground was saturated, and there was a great difficulty about lifting and harvesting the corms. It is well known that there are certain times for the flowering, and I think the time for lifting the corms may be regulated accordingly. The dry month of September greatly facilitated the ripening of the corms, a process which the wet October has considerably hampered. I have taken up a few of the very earliest, such as Shakespeare, Adolphe Brogniart, but the greater portion will have to remain, so that I shall be in no hurry about them, for if they are harvested by the end of November I shall be satisfied. There is one thing, however, about which care will have to be taken; the beds are now so thoroughly wet and the corms so full of moisture that if frost should come they will have to be protected by long litter thrown over them. I still adhere to the plan of storing them that I have for some years advocated—viz., to clear off all the earth which is dry enough, where it is considered advisable to rub off the spawn and store it away in bags, although I would strongly urge, except in the case of the newer and more expensive kinds, that it is not worth while to take the trouble, as they can be obtained now at so cheap a rate, and instead of having to wait for two or three years for your plants to flower you obtain flowering roots at once. Having cleared away the old corm and made the new one generally tidy, I then place them in my lattice frame where they are well

exposed to the light and air, first of all writing the name on each, so that if they get out of their place they will not create confusion. I bring the stand into the dwelling house, where it is free from the influence of frost, and where I can have an occasional look at them during the winter. With regard to the question of leaving them in the ground, I cannot recommend it. I have tried it more than once, and have always failed, and yet I have some coming up in the most vigorous style in my Rose garden, where I grew them ten or twelve years ago, these being evidently from spawn which has remained in the ground all that time. One corm has thrown up four strong flowering stems, yet with all this I should be very sorry to try to leave them in the ground.

With regard to the preparation of the ground for planting, it will be somewhat of a difficulty with me this year owing to our excessive rainfall, and the consequently sodden condition of the ground, but it must be done as soon as possible. After trying various parts of the garden I have chosen a piece where the soil is somewhat stiffer than the rest, and here I have a space sufficient for four beds, two of them I use each year, and this is the only change I can give them. The beds I have used this year will be planted with Potatoes or other vegetables, while those to be planted in spring have been this year occupied by vegetables. I believe it is still better to leave the ground intended for next year's planting fallow, but unfortunately I have not space enough to do this, so I must only do the best I can.

One important matter will occupy the mind of the grower, and that is the improvement of his collection by new varieties, for the improvement that is taking place is so very great that many of the choicest varieties of former days are shelved by others of the same colour. Thus Norma used to be considered the best of the whites, and is still a pretty flower, but it has been supplanted by Enchanteresse, a flower double its size, and of excellent quality. Meyerbeer, which is still an exhibition flower, has a very successful rival in Grande Rouge, very similar to it in colour, but much larger, and so with many others; in fact, we are now getting a length of spike and size of flower which were undreamt of in former days.

I have had this year the opportunity of growing seedling varieties from four different sources. I met at the Crystal Palace in 1888 an American nurseryman who kindly offered to send me some of the new American varieties. In due course I received a dozen fine corms, but I am sorry to say that I found nothing of any moment amongst them; they were deficient in form and length of spike, and although one or two varieties were curious in colouring, yet they were so angular in shape that it was impossible to regard them as worth keeping, and they have now gone into mixtures. The other three sources were Messrs. Souillard and Brunelet of Fontainebleau, Mr. Kelway of Langport, and Mr. Burrell of Cambridge. Mr. Kelway sent out as usual a number of new varieties which had been certificated in various places, but I do not know enough to be able to say anything about them. I have grown some of those sent out in 1886, but I have not grown any of the more recent ones. He has been successfully exhibiting his flowers in Paris, so I have no doubt they were good, and amongst the varieties of 1886 there are unquestionably some pretty sorts.

Of Mr. Burrell's seedlings I know more, and am quite convinced that he is raising some most valuable varieties, and although they have not been announced in his catalogue, that does not detract from their excellence. The truth is, I suppose, that bringing out seedling varieties of the Gladiolus is not a very paying concern, and Mr. Burrell is somewhat fastidious. He does not like to bring forward anything that is not thoroughly good. I have grown some of his for the last two years, and think that amongst them the following may be noted as really good:—

Cygnets.—A creamy white flower of good size and substance, and giving a good spike.

The Mikado.—A brilliant scarlet flower with white spot and carmine feather.

Avalanche.—A pure white with long spike of large flowers, opening very much at the same time.

Snowdon.—I have not seen Souchet's Mont Blanc, and this is by far the finest white Gladiolus I have seen; the flowers are very large, and it was exhibited at Shrewsbury with twenty blooms out on it.

Mrs. Lindsell.—A flower much in the style of Orphée, but larger and very brightly marked.

Dorothy and Pleasance are also good flowers, while several of the selected seedlings of last year promise to make good flowers. I now come to the French varieties, of which I have had none later than those sent out in the autumn of 1887, and of them I think the following a correct account:—

Arrière Garde.—A late blooming variety; plant is strong and forms a good long spike of salmon rose flowers, largely flamed with slaty violet, white spots.

Cendrillon.—A long spike of flowers closely set together;

flowers large, although somewhat angular in form, bluish white, largely flushed and striped with rosy carmine; very vigorous and curious looking, late blooming.

Enchanteresse.—Sent out in 1886; a very fine white flower of large size and substance, and of good form; a very remarkable flower.

Gregoire.—Large flowers, largely lined and striped with carmine on a white ground, large and rich carmine spots; a very effective flower.

Formosa.—An early flowering variety, holding itself well; tender rose flesh and satiny looking, slightly striped with orange on the border of the petals.

Docteur Bailly.—Long and fine spike of large flowers, brilliant scarlet with a small carmine spot on a white ground.

Jubilée.—Large carmine flowers, opening all its flowers nearly at the same time, flowers often coming semi-double.

Panama.—Long spike of large flowers, beautifully set, intense rosy carmine, striped and shaded with bright scarlet.

Picador.—Long and regular spike of scarlet flowers, pure white spot; plant of fine effect.

Aurore de Feu.—Brilliant spike of bright rose coloured flowers with centre yellow, and of a very peculiar colour; very distinct.—*D., Deal.*

OPEN QUARTERS FOR VEGETABLES.

It has long been my opinion that the value of garden walls, as regards the shelter they afford to the vegetable quarters enclosed by them, has been greatly overrated, and every season fresh observations in various parts of the country still further convince me that there is much less need for them than is generally thought to be the case. If they were absolutely indispensable for the production of choice hardy fruit, and more especially Pears, Peaches, Plums, Apricots, and Cherries, there would yet be a strong argument in favour of the erection of the orthodox high garden walls; but it has repeatedly been demonstrated with how much greater certainty very superior fruit can be grown in cheaply constructed glazed houses, and there is therefore no need for me to emphasise the point. A garden wall to be of real service ought to be substantially built, and not much under 12 feet in height, and such proves somewhat expensive. In some districts, and by good management, the garden walls are well furnished with profitable fruit trees, and in some instances they may be of good service in protecting and forwarding vegetable crops located near them. As a rule, however, vegetables can be had quite as early in the open, always provided a suitable site is selected for them. Take Peas for instance. Grown near a sunny wall they apparently soon surpass any that may have been sown at the same time in a sunny open spot, but in the end the latter can be gathered from quite as early as those presumably more favoured, and are quite as productive without being nearly so tall. I have repeatedly attempted to obtain Peas from borders sheltered by high walls earlier than friends from the open fields in Essex, but never succeeded in doing so unless recourse was had to raising the plants under glass and other coddling measures. Shelter favours the growth of haulm rather than the crops, and varieties that under garden culture attain a height of not less than 4 feet rarely exceed 2 feet in the open fields. In few instances do the former have the advantage in the number of pods produced, and if they happen to be somewhat longer they are not always so well filled. The later rows of Peas in much sheltered gardens are very liable to be overrun by mildew, but if grown in an open position and given good room they are far more healthy and productive. Much of the foregoing also applies to Runner Beans, the plants grown in the open fields being in full bearing long before the majority of the rows in private gardens are largely gathered from, and it is only in open positions that the plan of growing the Beans without stakes answers well, richness of soil and shelter combined causing the growth of too much haulm. Kidney Beans again, if well exposed to the light and air, are wonderfully sturdy and productive. Some idea of the productiveness of Beans as grown in the open fields may be gained by sowing a single row on the ridges between the Celery trenches—a plan also much in vogue with the market growers, who annually send many tons of pods to the markets as well as to pickle manufacturers.

It is not poverty of soil, or the use of a comparatively small amount of manure that is responsible for the sturdy growth in the case of the various crops grown in the open plots of ground, as in many instances the market growers are extremely liberal with solid manure, wonderfully so in fact, the quality of this manure being also superior to much that private gardeners have to be content with. Cauliflowers in the open heart in quickly, and so also do Cabbages and Lettuces; and other crops are similarly precocious, being yet of full size and excellent quality. When any of these are found to be tough or strongly flavoured it is either the

fault of the cook, or it is owing to their being too long exposed in the markets and shops. To further strengthen my argument in favour of more open quarters for the ordinary occupants of the kitchen garden I would also mention the fact of having once served a gentleman who could always detect whether the Strawberries sent to the dining table were gathered from the plants in his private gardens, or were obtained from the open fields rented from him. The latter were invariably superior, the varieties being the same, to anything I could grow in the garden, and we were never successful in producing nearly such heavy crops as emanated from the sturdy plants in the open fields. Some of the best Potatoes I have ever tasted were bought from an Essex farmer, who manured the ground very heavily (it was put on steaming hot) at planting time, and very heavy crops were lifted. This season I noted how much better the Potatoes in the open fields withstood disease than did ours between walls and a hedge, the haulm of the former being quite green after ours was dead. Even Asparagus, which is supposed to require shelter from high winds, is no more liable to be twisted about and injured in a walled-in garden than in the open, the former really standing more in need of staking than the more sturdy plants grown without other shelter than they afford each other. Ridge Cucumbers and Vegetable Marrows if lightly sheltered at the outset are much the most productive in the open fields sloping southwards, and almost any kind of vegetable can be grown successfully in these positions.

As regards hardiness, the superiority of the crops grown in the open fields must be admitted. Not unfrequently the whole of the Broccoli in walled-in kitchen gardens are destroyed by frosts, while the bulk of the plants grown in the open fields escape with a severe "shaking" only. The former are usually too long in the stem to be hardy, this being the most vital part of the plant. Those in the open fields are certainly given more room than many private growers think necessary, but from the seed bed till fully grown they are very sturdy, the stems being eventually well protected by the leaves. Prior to the introduction of superior forms of Brussels Sprouts the plants grown in the majority of kitchen gardens were by no means generally productive, but our market-growing friends could point to many acres of the Old Imported, or any form supplied to them as such, that would equal anything to be seen at the present day. Plenty of light and air and a firm root run favoured a sturdy productive growth, and in those days exceptionally profitable crops were obtained. The breadths of vegetable crops generally growing in the open fields usually present a remarkably even appearance, and in nearly every instance a marked absence of superfluous leaf growth is noticeable. If, therefore, I have proved my case, those who are about to form a new kitchen garden ought not to be in too great a hurry in building garden walls, while those who possess them already should not attribute too much to the shelter they have afforded the vegetable crops within their influence.—W. JGGULDEN.

THE CHISWICK CENTENARY CONFERENCE.

CERTIFICATES of merit were awarded to the following new varieties of Chrysanthemums at the Conference on November 5th and 6th:—

NEW VARIETIES.

Aurora (single), Etoile de Lyon (Japanese), M. E. A. Carrière (Japanese), Bombardier (decorative), Souvenir de Londres (single), Mons. Bernard (Japanese), Miss M. A. Haggis (incurved), Violet Tomlin (incurved), and Lune Fleuri (Pompon), from Messrs. H. Cannell & Son. Thomas Stephenson (Japanese), Mrs. Judge Benediet (Ancmonce), Rose Owen (single), Lily Owen (single), and Lune Fleuri (Pompon), from Mr. R. Owen. Alice Stevens (Pompon), and Violet Tomlin (incurved), from Mr. G. Stevens. Mrs. Alpheus Harly (Japanese), from Mr. T. S. Warc. Mrs. F. Jameson (Japanese), Mons. Bernard (Japanese), Etoile de Lyon (Japanese), Admiral Symonds (single), Edie (single), Violet Tomlin (incurved), Miss M. A. Haggis (incurved), James Weston (Japanese Ancmonce), and Souvenir de Londres (single), from Mr. E. Molyneux. Stanstead White (Japanese), and Mrs. F. Jameson (Japanese), from Mr. R. F. Jameson. Annie Clibran (Japanese), L'Automne (Japanese), and Thomas Stephenson (Japanese), from Messrs. Clibran & Son.

ESTABLISHED VARIETIES.

Incurved.—Golden Empress, Golden Queen of England, John Salter, Alfred Salter, Lord Alcester, Princess of Wales, Mrs. W. Shipman, Queen of England, and Empress of India from Mr. E. Molyneux. Mr.

Brunlees from Mr. E. Berry. Lord Wolseley and Hero of Stoke Newington from Mr. Wildsmith. Barbara, from Mr. C. J. Salter.

Japanese.—Edwin Molyneux, Madame C. Audiguer, Sunflower, Jeanne Délaux, Mlle. Lacroix, and Madame Laing, from Mr. E. Molyneux. L'Adorable, M. Astorg, M. Freeman, from Mr. C. J. Salter. Japonais, Criterion, Thunberg, and Bertha Flight, from Mr. Wills.

Japanese Anemone.—Fabian de Mediana from Mr. C. J. Salter. Souvenir de Madame Blandinières and Jeanne Marty from Messrs. Paul & Son.

Show Anemone.—J. Thorp, jun., from Mr. R. Parker; Fleur de Marie, Empress, and Nelson from Mr. E. Molyneux.

Pompon.—Mlle. Elise Dordan, Toussaint Maurissott and Mlle. Marthe from Mr. C. J. Salter; Prince of Orange, Cendrillon, Marabout, Nelly Rainford, Black Douglas, Eleonore and Rosinante from Mr. C. Gibson.

Anemone Pompon.—Briolis, Regulus and Antonius from Mr. E. Molyneux; Astrea, Madame Grutien and Calliope from Mr. C. J. Salter; Val d'Andorre and Roi de Japonais from Mr. G. Barnett.

Japanese reflected.—Elaine from Mr. J. Doughty; Maiden's Blush from Mr. E. Berry.

Japanese.—Ralph Brocklebank from Mr. W. Wildsmith; Belle Paule and Boule d'Or from Mr. Jameson; Avalanche from Mr. Fyfe.

Reflected.—Phidias and Mr. Forsyth from Mr. E. Molyneux; King of the Crimson, William Earley and Mrs. Mayes from Mr. C. J. Salter; Cloth of Gold and Chevalier Damage from Mr. W. Wildsmith.

Anemone, large.—Miss Annie Lowe, Gluck, Lady Margaret, Grand d'Alvéole and La Marguerite from Mr. C. J. Salter.

APPLIANCES.

Certificates of merit were granted to Mr. F. Jameson for spring cup raisers and nare holder; to Mr. Harland for a cup raiser.

CONFERENCE PAPERS.

UNDOUBTEDLY the chief feature of the Chiswick Conference last week was the reading of papers. Mr. Haywood's presidential address was in every respect admirable, but the author was unable to deliver it in consequence of a throat affection, but it was effectively read by Mr. Wilks, who also made himself distinctly heard throughout the great vinery in reading Mr. Harman Payne's able, yet necessarily condensed history of the flower. Mr. Molyneux gave his estimate of new varieties, and grouped them into first and second class sections. Mr. Wright and Mr. Shirley Hibberd followed, the first day's proceedings terminating with a vote of thanks agreeably proposed by Dr. Masters to the chairman and readers of the papers. On the second day Mr. Hemsley discoursed learnedly on species of Chrysanthemums, Mr. F. W. Burbridge exhaustively on seeds and seedlings, and Messrs. C. Orchard, C. Pearson, and W. Piercy practically and ably on dwarfing and grouping Chrysanthemums, market Chrysanthemums, and summer Chrysanthemums respectively, Mr. Shirley Hibberd presiding. There was unfortunately no discussion. The papers were, perhaps, fully too long, and a synopsis of them is necessary for distributing through a meeting for purposes of discussion. We have only received transcripts of two of them, which follow. There was a large attendance. The papers will be published in the Journal of the Royal Horticultural Society, which will be sent to Fellows of the Society who desire to have copies.

PROGRESS IN CHRYSANTHEMUMS.

MR. SHIRLEY HIBBERD'S paper given in the Conference under the above somewhat vague title, treated of the evolution of the flower as illustrated in its development in European gardens in the last 100 years. He said a flower of this kind was removed by man as far as possible from natural influences, and the direction of its development was in great part determined by the cultivator's taste. It was especially worthy of observation in entering upon the subject that we did not, as makers of the flower, begin with the wild forms that man had not till then touched; but we began with an old favourite of the gardens of China, the Corea and Japan, and not only so, but all the several types of reflected, incurved, Japanese, and Anemone flowers were established in the east ages before the west knew of their existence. Many fine varieties that would not be classed as Japanese were obtained from China in the early days of the present century, and there was no evidence to be found in the history of the occurrence of a new type as the result of European cultivation. Comparing early with late flowers, however, the differences were enormous; all the early kinds were rough and wanting in dignity as compared with those that had found favour in Europe in the last fifty years.

The multiplicity of types and styles was advantageous as affording scope for the exercise of a variety of tastes. When the Japs were coming in like a flood in the days of Mr. Salter, the London florists objected to them on the ground of their extravagant departure from the code of properties that then prevailed, being so enamoured of the incurved flowers as to need time to discover beauty in the new comers. But a school of florists in the south of France hailed the innovation with joy, and Frenchmen who had failed to find in the incurved flowers the properties that pleased them took to the Japs, and quickly produced a magnificent series of new varieties, the effect of which on the mind of Europe was to establish the Chrysanthemum in the highest degree of popularity as a florist's flower. The men were in each case better than the schools that owned them, and they learned to perceive in each other's special favourites rights to divide honours with their own.

Regarding the dark reflexed Kiku, figured in "B. M." 327, as the

first of its group, it would be found that Involutum, or Curled Lilac, figured by Sweet, 1823, might be regarded as the first proper incurved flower. The first of the Japs was undoubtedly the quilled flamed yellow, introduced from China by Captain Drummond for the Horticultural Society in the year 1820. A number of examples were given of Anemones, Anemone Pompons, and Liliputians, and the structure of the flower was explained with special reference to the organs of reproduction. Beginning, then, with the types ready formed, it will be seen that the European florists have in less than a hundred years accomplished more for the flowers than the Chinese cultivators in the thousands of years during which they profess to have regarded it as a favourite. They had a circle to begin with as in the case of any asteraceous flower, but out of this simple form they had evolved infinite variety, for while a perfect incurved flower differed so greatly from a fantastic Jap, the same fundamental lines were traceable in both, were essential to both, and the variations consisted in added adornments. But geographical influences co-operate with diversity of tastes in the fashioning of the flower. The general tendency of taste in raising and selecting is to sterilise it, and the incurved represent the most completely sterilised form; while the Anemone centred is a form in which fertile florets occur not by accident, but as an integral part of the true model. The Corea is a cold country, and Japan is a cold country, and their climates had contributed to the sterilisation which, in the case of the incurved had been completed by British cultivators. Indeed this, the most perfect, the most satisfying, and the most exacting of all forms of the flower known to us, is really a cold climate form, as our friends in the south of France discovered in its refusal to be managed by them; while on the other hand the Japanese type in their hands became as a new creation. These facts are of vital importance in the study of the making of this grandest of all florists' flowers. If we are to have new forms, we must have fertile flowers to begin with; and we must cease to disbud, give no preference to this or that bud, allow the plant to show its flowers, and as the climate is too cold for seeding, we must make a climate for the purpose. English cultivators have hoped for seed from incurved flowers of the noblest forms and proportions, in accordance with the Shakespearean motto, "From fairest flowers we desire increase," but a first-class incurved flower was as incapable of producing seed as the bud that never opened.

But we are not entirely dependant on seed for new varieties, for this is a sportive plant, and a considerable proportion of our gains in new varieties have been by means independent of the cultivator who has only had to keep what Nature gave him without his asking. Sports were probably of seminal origin; in other words, they represented the parentage on one side or farther back than the immediate progenitors, and the occurrence of the sports that appeared to be identical at different places at the same time seemed to prove that the quality newly exhibited in the sport was an inheritance, and of strictly seminal origin.

Looking to the future, Mr. Hibberd discussed at some length the developments that might be anticipated. Referring to a figure in the "Keramic Arts of Japan," and to one of the customary blue Chrysanthemums on a Japanese Cloisonné jar that he placed upon the table, he said we might hope for a much nearer approach to blue and to red than any flowers had as yet shown, but it was unlikely and perhaps undesirable that high positive tones of blue or scarlet should appear. We may hope for more blue and more red, and for the full development of an agreeable odour. The asteraceous order is characterised by the production of aromatic principles that often are far from pleasant, and our favourite is given to the manufacture of an odour that reminds one of Camomiles. But a very trifling variation in the constituents of aromatic substances would often make all the difference between odours that create disgust or that give delight, and there were a few examples of pleasantly scented mums to encourage us. We had gone forward in the development of form, but we should have to go backward to obtain anything like a new departure, for all our forward work tends directly to sterilise the flower and to bar all further progress.

JUDGING CHRYSANTHEMUMS.

MEN AND METHODS.

MR. WRIGHT in his paper first treated on men and the qualifications as judges, then indicated the merits and demerits of groups and specimen plants; and, lastly, dwelt on methods of procedure and the properties of blooms. He said: A season seldom, if ever, passed without the qualifications of persons who are appointed to officiate as judges at the chief Chrysanthemum shows being questioned by writers in the gardening press. To that he had not the slightest objection, as honest criticism was wholesome in taking conceit out of men, and putting them on their mettle in the work they undertake. He went on to ask—Who are the objectors, and what is their experience? Who are the judges, and what are their credentials? Who are those who make the appointments, and what are their qualifications? And answered those questions in a somewhat trenchant way.

Proceeding, he remarked that, apart from technical knowledge, a judge must be absolutely without sympathy at a critical moment. Whether he knows to whom the plants or blooms belong or not, he must seal his soul against all feeling in favour of a particular man. If there be one point against the products of his friend or neighbour he must give it against him as if he were an enemy. Judges, he said, had nothing whatever to do with exhibitors, but only with exhibits. This was one of the hardest lessons that local judges at local shows had to learn, and he related some experiences bearing on this matter, con-

cluding this portion of his paper by saying he was all in favour of the training of young men for the important work in question, "but they must be men of intelligence and high character; of the strictest probity, absolute impartiality, and who can completely banish from their minds all thoughts of individuals, and concentrate their whole attention on the produce before them, with the object of doing strict justice to all. They must be prepared to incur displeasure and even abuse; but if they act honestly and make few or no mistakes, the opposition of disappointed men will be lightly regarded, and instead of its having a weakening will have a strengthening effect on them as adjudicators."

Turning to methods of judging, he said, generally speaking, and for practical purposes there were three distinct forms of exhibits in a Chrysanthemum show:—Groups of plants arranged for effect; trained specimen plants; cut blooms arranged in stands. What was said on the merits and defects of groups can only be epitomised here:—"High quality blooms, fresh bold foliage, no unsightly stakes and stems, with freedom in arrangement, and pot exposure reduced to a minimum, are the chief factors in a first-rate group of Chrysanthemums, and in proportion as they are represented so will the prizes be awarded."

He next passed to trained specimen plants, and said that in no other form was high culture with skilful manipulation better displayed than in the production of the best examples. But many were faulty in training. In alluding to good exhibits at different shows the following tribute was paid to a successful grower:—"I am sure all here who were acquainted with the late Mr. W. Hall of Brixton would if they could scatter over his grave a few of the flowers which he loved and grew so well. His grave is in the deep waters, but his gentleness of spirit, kindness of heart, devotedness to his calling, and skill as a grower of specimen Chrysanthemums, will not die while those who knew him best and the excellence of his work, live to labour in the floral world. When he exhibited a few years ago his were model plants—not widely spread out as if to say, 'look how big I am,' but massive in stems, leaves, and blooms—compact without being huddled, and in which Art and Nature were so merged that there was not visible line of conflict between them. Not a twisted stem could be seen in those beautiful specimens, about 2 feet high, and bearing from eighteen to two dozen or more blooms equalling those in first prize stands, and a mass of dark leaves hanging like thick drapery all round, half hiding the pots. Those are the specimens to which judges award silver cups, and the nearer plants approach them in excellence the greater is the pleasure in granting to them the awards they merit."

Cut blooms were next alluded to. The advance in these during the last fifteen years had been marvellous. The best stands of incurved and Japanese varieties even a dozen years ago would not have the remotest chance of winning third prizes now in the best competition. Exhibitors had increased in equal ratio, and at no period in the history of the Chrysanthemum was the standard of excellence as represented in stands of cut blooms so high as it is now. That compelled judges to exercise the greatest discrimination and adopt the best methods known to them in placing the competing stands in their right positions.

Judging by guesswork would not do nowadays in large close contests, and unless the differences in value are obvious to every judge pointing should be resorted to. An instance of its necessity was then given, and different methods indicated. Giving equal prizes was condemned as an easy way out of a difficulty, but almost always unjust to one of the exhibitors. When a silver cup was provided it was either won or lost. When a prize is offered for the champion bloom in a show it is found. He had never known a draw in such a case, and the honour divided between two blooms. If a mark of superiority could be found in one bloom surely it could be in a second and a third, and so on. That, he thought, ought to settle the matter on giving equal prizes. Mr. Wright concluded:—"Do you ask what kind of blooms score the most points? I answer, Not necessarily the largest in the incurved section if they are loose, flat, rough, or stale. They must possess depth in proportion with width, firmness, freshness, brightness, clearness, and smartness. There is the difference, to use a familiar simile, between the well formed, well groomed, fine upstanding hunter, and the rough, shaggy, burly, slouching carthorse. How to produce and present the blooms in the best form is a question for cultivators."

JUDGES AT EXHIBITIONS.

As an exhibitor I should like to protest against the manner in which some judges handle the cut blooms which they are adjudicating upon. Surely it is sufficient to take them out of the stands to examine them critically in close contests without resorting to shaking them savagely as a terrier would a rat, pressing outwards the centre petals, presumably to see if the blooms contain an eye. For what other reason I am at a loss to know they thus treat blooms in the manner named. I cannot help thinking that judges who do as I have seen and described cannot have had any experience with the preparation of cut blooms for exhibition, or they would not give pain by such barbarous treatment of blooms over which hours and perhaps a whole night has been spent in preparing for a show. There are two other reasons why blooms at exhibitions should not be treated in the manner indicated. First they are rendered useless for any other exhibition by having their petals bruised and displaced. Secondly, the public cannot look upon the flowers in their true character after they have been subjected to such unnecessary handling. Visitors are apt to remark, "How roughly Mr. So-and-so's blooms were staged!" through no fault of the exhibitor,

but entirely owing to the want of knowing better on the part of some judges.—AN EXHIBITOR.

CHRYSANTHEMUM MISS MARY ANDERSON.

SINGLE varieties of Chrysanthemums are coming steadily into favour, and they are worthy of all attention wherever flowers are largely employed for decorative purposes. They are easily grown, very free, and in the majority of cases extremely light and graceful—exactly adapted for arranging in vases or stands. One of the best of the section is the variety named Miss Mary Anderson, which has gained much favour

FIG. 49.—CHRYSANTHEMUM MISS MARY ANDERSON.

with many cultivators, and is greatly appreciated in Mr. Ware's nursery at Tottenham. The blooms are of moderate size and excellent form, the ray florets broad, a soft rosy blush at first, afterwards becoming pure white. The blooms are produced with astonishing freedom, some of the stems forming natural wreaths or bouquets. A spray from Tottenham is represented in fig. 49.

CHRYSANTHEMUMS AT CHILWELL.

JUDGING from the number of visitors to the above nurseries during Messrs. Pearson's annual exhibition, the Chrysanthemum is not at all likely to lose its popularity. The Show is unusually good this year, the large house set apart for the purpose being a mass of colour.

Upon entering some good trained specimens well arranged arrest attention. These are composed of standards, pyramids, flats, and bush trained plants. Perhaps amongst the most notable is a grand pyramid of Mrs. Stevens, with between two and three hundred flowers. Triomphe du Nord, Madame B. Pigny, and Bertier Rendatler are also very fine. Of novelties amongst American varieties of promise are Puritan, very good, W. W. Coler, a fine bold flower, reddish bronze in colour, and very distinct in form. George Atkinson is also likely to make a good exhibition variety, the blooms are large and of good form, delicate blush in colour. Mrs. Andrew Carnegie is opening, and promises to be as good as represented in the American Press. Of the other Japanese varieties the most notable are Sunflower, Florence Percy, Avalanche, very fine, though some of the finest flowers are past their best, as also are E. Molyneux, Comte de Germiny, and some others. Mdme. C. Audiguer, M. Bernard, Boule d'Or, Mdme. J. Laing, and its fine sport Sarah Owen, are in fine form, while Miss M. A. Haggis, Violet Tomlin, H. Shoesmith, Lord Alcester (the finest blooms in the Show), Princess Beatrice, Mrs. W. Shipman, John Salter, and Jeanne d'Arc, form the best of the incurved varieties, though it may be seen that Princess of Wales and Mrs. Heale have been very fine. Some novelties are worthy of notice amongst the Anemone class. Mdme. Robert Owen has the appearance of being the whitest Chrysanthemum in cultivation, Nelson, Sabine, Souvenir de Mdme. Blandinière, Jeanne Marty, and Miss Annie Lowe are all well represented. There are numbers grown as decorative plants, which are much admired, especially Wm. Holmes, Wm. Stevens, Source d'Or, Ornaments, Elaine, Sœur Melaine, Coquette de Castille, and the bright Anemone Thorpe junior. There is a large and fine show of fruit. The Zonal Pelargoniums are worth inspection. The Show remains open until the end of the month.—VISITOR.

DRESSING CHRYSANTHEMUM BLOOMS.

BLOOMS for dressing should be cut with a stem 6 inches longer than the tube in which the flower is to be placed, the extra length of stem being required for the operator to draw the bloom down into the tube. Some growers use tubes for the flowers which are not suitable. The flange should be as large as possible, without being seen under the edge of the florets. This is a support which is of advantage in setting off the florets to the best position, and retaining the bottom row stiff. Cut off the leaves from the stem, slip the stem through the tube, bringing the latter close up, but not pressing on the petals at first. Steel tweezers, from 3 to 5 inches long, are the best. The points should be narrow and rough for obtaining a firm grip of the petals without slipping, as is the case with those made from ivory. Care should be taken that the florets are not bruised in the operation by gripping them too tightly, as a light and steady hand is needed to dress the blooms properly. Take the flower in the left hand, and with the tweezers remove any florets that are damaged or out of place, or any that are too stiff to incurve. The top or centre is the correct place to commence dressing after the removal of the florets previously mentioned. If the florets there show an inclination to reflex, very gently draw the jaws of the forceps up to the edges of the florets from the base to the point. If this be done with care and good judgment the centre will be quite filled, while the florets in other parts of the bloom should be arranged as desired. The bloom should then be drawn down as tight in the tube as is necessary to prevent the florets moving out of their place, but in no wise should the bloom be drawn down so low as to reduce the depth of the bloom any more than is absolutely necessary for security. The stem should be fixed in the tube by means of a small piece of cork cut wedge-shaped, and in size according to the space between the stem and the size of the tube. If the cork is soaked in water before using it is softer and more easy to push into its place with the thumb. In conclusion I would advise beginners to practise freely upon various sorts of blooms, and then a knowledge will be gained as to how much pressure each variety will stand from the tweezers without bruising the florets, as there is a difference in the constitution of the petals of some kinds.—E. M. (in the *Chrysanthemum Annual*).

STAGING JAPANESE BLOOMS.

THE following is a very cheap way of staging Japanese blooms, as it does away with the necessity of using cups. As will be seen from the sketch (fig. 53) a piece of wire, No. 16 gauge, is twisted with as many spirals as may be required according to the size of the bloom, and the end is bent to fit into the cup, and the stem is fixed to the wire with bouquet wire. The advantages are that they cost next to nothing, and can be varied to suit a reflex flower like Criterion, which should be shown more or less flat, or if one of Mdme. Lacroix type by bending the wire the drooping character can be preserved.—GEO. WALKER, *Wimbledon*.

CHRYSANTHEMUM SHOWS.

Teddington, Putney, Chiswick, Cranbrook, and Birkenhead, Thursday, Nov. 14th.
Leicester, Eccles, Wellington (Somerset), and Cheshunt, Friday, Nov. 15th.
Bolton and Derby, Friday and Saturday, Nov. 15th and 16th.
Twickenham, Winchester, Liverpool, and Cardiff, Tuesday and Wednesday, Nov. 19th and 20th.
Rugby and Birmingham, Wednesday and Thursday, Nov. 20th and 21st.
Falmouth, Wednesday, Thursday, and Friday, Nov. 20th, 21st, and 22nd.
Hull (National Society's Provincial Show), Thursday and Friday, Nov. 21st and 22nd.
Chorley and Stockport, Friday and Saturday, Nov. 22nd and 23rd.
Pontefract, Thursday, Nov. 23th.

EXHIBITION APPLIANCES.

FROM Mr. R. F. Jameson, Hesse, Hull, we have received samples of two useful appliances for the assistance of exhibitors. They have both been patented. When exhibited at the Royal Horticultural Society's Chiswick Conference and the Crystal Palace Show they received the commendations of the Judges.

The new Jameson spring cup support (figs. 50 and 51), consisting

FIGS. 50 AND 51.—SPRING CUP SUPPORT.

of a circular plate with two springs attached, is screwed underneath each hole of the show tray, and the two springs grasp the cups one on each side as it is passed through the hole, retaining it at any desired height. This cup support is an improvement on the cup with springs inside, which Mr. Jameson introduced two or three years ago, inasmuch as it cannot draw the stem of the bloom out of the water, and as it adapts itself automatically to cups of various sizes it can be used with exhibitors' old cups.

FIG. 52.—NAME CARD HOLDER.

The "Name Card Holder" (fig. 52) contains three cards, one holder being placed behind each row of blooms. To attach the holder to the tray fasten two round-headed screws, one close behind the other, at the back of each row of blooms, slip the foot of the holder at the widest part over the two screws, draw it forward, and it is perfectly firm, but can instantly be slipped back and detached for travelling or other purposes.

ROYAL HORTICULTURAL SOCIETY.

NOVEMBER 5TH.

SCIENTIFIC COMMITTEE.—Present—Mr. Michael (in the chair), Mr. Burbidge, Mr. Veitch, Mr. Pascoe, Mr. O'Brien, Dr. Müller, Dr. Oliver, Dr. Masters, and Rev. G. Henslow, Hon. Sec.

Monstrous Chrysanthemums.—Mr. Burbidge exhibited two flowers, in one of which the corollas had become partly virescent and distorted; in the other they were surrounded by a numerous progeny of buds, producing the "hen and chicken" form. The question was raised as to the possibility of fixing such peculiar monstrosities by breeding. It was observed by Mr. Veitch that a tendency to doubling is secured and intensified by self-fertilisation, as occurred in the Balsamiflorum section of his East Indian Rhododendrons. Mr. O'Brien remarked that the first double Begonias were secured in precisely the same way. Observations were made on the possibility of the effects of mechanical injury to plants being hereditary. It was the belief of Mr. O'Brien that Ferns may become tasselled, and transmit that feature solely from repeated injury to the fronds, judging from a case within his experience. Mr. Burbidge also corroborated the belief that irritations which are prolonged tend to produce effects which may be transmitted to the offspring. The cause of the monstrous condition of the specimens exhibited was thought to be over-nutrition, judging from the gross nature of the foliage, &c.

Origin of Chrysanthemum.—A communication was read from Mr. Hemsley, in which he recorded the fact that the earliest specific name given to the Chrysanthemum was not sinense, but morifolium, by Ramatuelle, C. indicum being supposed to be a distinct species. Mr. Burbidge, however, observed that of seedlings from any Chrysanthemum, forms apparently identical with C. indicum, which is a native of China, always arise, leading to the supposition that this latter species is the real origin of both kinds in cultivation. All wild specimens are yellow and single, the other colours having arisen by cultivation.

Orchids Exhibited.—Mr. O'Brien showed the following plants, which were received from Mr. Tautz of Hammersmith:—*Cynoches barbatum*. This first flowered in 1849 with Mrs. Lawrence of Ealing Park. It was (if dimorphic as other species) presumably the male form. A botanical certificate was unanimously awarded. *Stelis micrantha*, a minute flowering plant; *Trichosma suaveolens*, trilabella, this being one of several Orchids now cultivated, with a tendency to Peloria, in that the two other petals are more or less coloured like the labellum.

Indico-javanicum, bigener.—Mr. Henslow described the foliage of this cross, exhibited by Mr. Veitch at the last meeting. Though smaller in size the leaf agreed both in form and anatomical details with

that of the *Rhododendron*, or female parent, in every detail of importance. That of the *Azalea* was markedly different, being obovate instead of lanceolate; toothed and not entire; covered with fibrous hairs instead of being glabrous above, with minute peltate scales below; the cell-walls of the epidermis being sinuate instead of straight; and the proportion of stomata being less than in the *Rhododendron* as well as the cross. The hairs of *Azalea* are very peculiar in structure. They grow on the branches, petioles, midrib, and veins below, and generally scattered over the upper surface of the leaf. They are composed of numerous fibres resembling short liber-fibres, graduated in length so that the longest form the point of the hair. Mr. Henslow observed that he could not discover any previous description of such a structure, which appears to have been hitherto overlooked. He also examined the foliage of the dwarf plant, sister to the above cross. The anatomical details exhibited a very considerable amount of arrest of structure, the number of cells being nearly twice that of the *Rhododendron* in consequence of their minute size, with fewer stomata. It also agreed in most other respects both with the sister-cross, as well as with the *Rhododendron*, except that the shape was more elliptical, and possessed glandular hairs instead of peltate scales. It was observable that this cross followed the supposed rule that the female parent imparted its likeness to the foliage, while the male parent supplied that of the flowers. Mr. Henslow observed that in the 150 hybrids and crosses raised by Mr. Veitch, amongst seven East Indian species of *Rhododendron*, the rule was found to fail entirely, in that each parent would impart certain peculiarities either to the flowers or leaves, according to its own prepotency, but the cause of such a power was at present unknown.

Reversion in Potatoes.—At a meeting of the Scientific Committee on November 13th, 1888, Mr. W. G. Smith exhibited a Potato which was the result of a reversion. Mr. Fenn had crossed two long sorts of kidney Potatoes—viz., Early Coldstream and the Early Ashleaf. The result was a globular form which he called W. G. Smith. After eighteen years, during which this had come true, one plant suddenly reverted to the original type. The specimen exhibited was $5\frac{1}{2}$ inches long, the round one being about $2\frac{1}{2}$ inches in diameter. Mr. Henslow planted these tubers in March, 1889, and the round Potato yielded only 1 lb. 8 ozs. of small tubers; the long one, planted by the side of it, gave 6 lbs. of large sized tubers. Not only were the tubers true to their kinds, but the foliage was very distinct.

Clematis Vitalba.—Mr. Henslow exhibited a photograph of, and described a plant of the Traveller's Joy, or Old Man's Beard, which grows in his garden near Drayton Green, Ealing. It is evidently of great age, as the stem at the base is about 9 inches in circumference. From this proceed several thick branches; half of the plant then spreads over a thick Holly hedge about 5 to 8 feet in height. The *Clematis* extends to about 30 feet each way, completely covering it with foliage and dense masses of blossom. One branch crosses an arched trellis and climbs to the roof of the house, whence, intermingling with Virginian Creeper, hangs in long festoons to the ground. The superficial area covered by the part on the hedge alone is about 150 square yards. The remarkable feature in the case is the enormous and vigorous growth the *Clematis* has made, and yet it is in ground with only a foot or two of earth over fine red gravel, constituting the uppermost and most ancient of the gravel beds of the Thames, there being, as far as is known, not a trace of calcareous matter in the soil. Nevertheless, the plant is usually described as a chalk-loving species. At all events, it is found abundantly on the chalk of Kent, the oolitic limestones near Cheltenham, and the carboniferous limestone near Bristol, &c. Mr. Burbidge suggested that it was just possible, growing so close to the house, that there might have been buried there a quantity of old mortar, &c. The ground, however, was lately excavated for a drain within 4 and 10 feet, when nothing but red gravel was exposed.

FRUIT COMMITTEE.—Present—John Lee, Esq., in the chair; and Messrs. H. J. Veitch, G. W. Cummins, F. Q. Lane, H. Balderson, W. Bates, G. Wythes, W. Wildsmith, J. Hudson, W. Denning, and J. T. Saltmarsh. Mr. W. Miller, gardener to Lord Foley, Ruxley Lodge, Esher, sent a basket of clean and excellent Mushrooms grown on an outside bed spawned in September. Mr. G. Wythes, The Gardens, Syon House, sent a good ripe fruit of *Monstera deliciosa*, for which a cultural commendation was unanimously awarded. Mr. H. Balderson sent bunches of ten varieties of Grapes cut from one house. The varieties were Alicante, Gros Colman, Madresfield Court, Foster's Seedling, Golden Champion, Trebbiano, Black Hamburg, Duchess of Buccleuch, Muscat of Alexandria, and Mrs. Pinck. Some of them were very good, especially the Muscats, and fine berries of Golden Champion. A vote of thanks was accorded. The Brussels Sprouts growing in the garden were examined by the Committee. Three marks of merit were recorded for Paris Market (Vilmorin) and Northaw Prize, two marks being placed to Veitch's Exhibition and Early Dwarf Paris Market (Oakshott & Millard).

FLORAL AND ORCHID COMMITTEE.—Present—W. Marshall, Esq., in the chair; and Messrs. Shirley Hibberd, W. Holmes, G. Paul, J. O'Brien, H. M. Pollett, J. Laing, P. Blair, H. Turner, J. Walker, H. Herbst, F. W. Burbidge, and C. Noble.

A magnificent collection of Carnations in pots was exhibited by Mr. Jennings, gardener to Leopold de Rothschild, Esq., Ascot. The variety was named Miss Joliffe Improved. All the plants were blooming with great freedom, and a silver medal was awarded. A cultural commendation was awarded to *Begonia Adonis* as a winter flowering variety. It was exhibited by Messrs. J. Veitch & Sons, and had previously received

a first-class certificate. The Orchids exhibited by Mr. Cowley, gardener to F. G. Tautz, Esq., were referred to the Scientific Committee, which see.

THE CULTURE OF ACHIMENES.

IN small gardens, where the stove is made to contribute not only to its own embellishment but to the adorning of the greenhouse and sitting-room during the summer, few races of plants can present greater claims to the attention of the amateur than those included in the natural order of the Gesneraceæ. This statement will more particularly apply to those plants possessing bulbous and scaly tubercles, such as the *Gloxinia*, the *Gesnera*, and the *Achimenes*, as they contain the following desirable requisites—They are easily cultivated; when well grown they are splendid in appearance; when brought into flower they will stand in any place under glass, partially shaded, until late in the autumn; they can be made

FIG 53.—CHRYSANTHEMUM BLOOM HOLDER.

to flower at almost any season; and, finally, when they cease flowering and the leaves decayed the tubers may be kept in a dry condition in any out-of-the-way place, provided the temperature does not fall below 40° .

We shall, for the present, confine ourselves to the *Achimenes* all of which species and varieties have scaly tubers.

Propagation can be effected by seeds, but unless for obtaining varieties by hybridising it is not worth saving, as even the leaves root freely. Small tubers are formed in the axils of the leaves of many of them, and, in all, plenty of full-sized tubers are found beneath the soil when the plants have finished their growth.

Instead of placing the tubers into their intended pots and boxes at once, it is better to place them in shallow pans, using any light soil just slightly moist, and doing little more than cover them. A little damp moss placed on the surface will be an advantage. Very little water should be given before the tubers begin to grow, after which it may be given more freely. By this method you will be enabled to choose the strongest growing plants for the centre of the pots. A temperature of about 60° should be maintained, and if early in the spring a little bottom heat would cause them to come all the better.

Shallow pans and boxes filled with plants will give plenty of bloom if well supplied with weak liquid manure, but the plants will flower longer and finer when grown in pots or boxes of the usual depth. A little earthing-up may then be given them at times. Attend well to the drainage, and cover the tubers when planted about an inch with the compost. Instead of placing them all over the pot, which, when they bloom, conveys nothing to the mind of the artistic, place the requisite number of tubers—three, five, seven, &c., according to the size of the pot—with their growing ends inclining to the centre, and the root ends to the circumference of the pot, similar to the spokes in a carriage wheel; and then the specimen, although not so in reality, will convey the idea of a single plant, and not look like a number of plants crowded together.

The soil should be light and rich; three parts loam, three parts peat, one of leaf mould, one of old dry cowdung, mixed together, riddled with a fine sieve—not to use, but to discard the finer particles—and then adding one part of silver sand and one of broken charcoal, will grow them admirably; placing the roughest part of the soil at the bottom, and covering the surface with the finer compost. Proportion the water to the growth. Where the roots have not reached the soil it must not be soaked. The whole family like heat, partial shade, and a moist atmosphere when growing. As the flowering state approaches inure them to more light and a drier atmosphere: neglect to do this, and you may have fine plants with clusters of tubers instead of blossoms. Nature, curbed in her efforts for reproduction one way, will attempt it by another. If you try them in dung frames extra care will be requisite, as the foliage will be injured if the steam and sun meet. Shade and air are the only remedies, or rather preventives. When they have flowered, and the foliage decayed, remove the tubers and preserve them in dry earth, or merely turn the pots on their sides. They must never be exposed to frost. Those started early this spring must be so employed next season; the different successions should therefore be marked. I have found them extremely useful for decorating greenhouses during the summer and stoves in the autumn. In warm sheltered places some of them would even succeed for a time out of doors.—R.

CYPRIPEDIUM INSIGNE.

AN old Orchid of no startling character, but when it is grown until the plants require 10-inch or 12-inch pots, and fill these well, it is very massive, particularly if each bears upwards of a hundred flowers. We have several plants like this, and they are as useful as any we possess at the present time. They are kept in a warm house in February, March, and April, hardened off in May, and stood in a cold frame from June until September, and when in flower we can let them remain in a room for six weeks without injury, but care is taken not to give them much water at the roots during that time.—M.

ONCIDIUM FORBESII.

THIS beautiful Oncid is now flowering in the collection of E. G. Wrigley, Esq., Victoria House, Dukinfield, where it is grown in an intermediate temperature. The plants are thriving in the ordinary teak baskets, and are flowering very freely, one plant carrying a spike of twenty-seven flowers. The sepals are obovate; the petals are larger and much undulated, both being of a bright chestnut brown, broadly margined, with broken lines of golden yellow. The lip, which is clawed, is larger than the petals, and of the same colour and markings. This makes a good companion to *O. crispum*, though it exceeds that variety for beauty and size of flower.—H. COOPER.

A FEW ANGRÆCUMS.

ONE of the small forms of the genus *Angræcum* is *A. Scottianum*, but none the less pretty on that account for its distinctness from allied species, and the delicacy of the flowers impart considerable interest to the plant; yet it is still somewhat rare, and I have only seen specimens in a few of the largest collections, but that is probably due to the fact that it has not been in this country long enough to permit very extensive propagation. When better known it will no doubt be included in most collections of moderate extent, as it deserves the attention of all growers who do not limit themselves to the merely showy Orchids. It is epiphytal in habit, with narrow terete leaves, very dissimilar from most other *Angræ-*

cums; they are tapering or awl-shaped, about 4 inches long, and one-eighth to a quarter of an inch in diameter, channelled in the upper surface and ridged below. The flowers are of a moderate size, very delicate in texture; the lip an inch or more across, pure white, with a narrow yellowish spur 3 to 4 inches long. The peduncle is slender and usually bears but one flower. The species is a native of the Comoro Islands, and I believe first flowered in this country at Walthamstow in 1878 in Mr. R. Scott's collection of Orchids, and in honour of that gentleman it has received its name.

A. pellucidum is from Sierra Leone, whence it was obtained by Messrs. Loddiges, and in their nursery it flowered in November, 1842. The plant is of rather bold habit, with large bright green leaves frequently exceeding a foot in length. The flowers are white, of a delicate semi-transparent texture, having a finely fringed labellum, and are produced closely on racemes of moderate length. Like the majority of species it usually flowers during the winter months, and thrives either on a block or in a basket suspended from the roof of a warm house. Though not by any means common it is fairly well known, and is included in most of the large trade collections. A coloured plate of it was published in the "Botanical Register" thirty-seven years ago, or about two years subsequent to its first flowering at Hackney.

Like the last-mentioned, *A. pertusum* is a native of Sierra Leone, but I do not know to whom is due the credit of first introducing it to England. It appears, however, to have been in cultivation several years before *A. pellucidum*, as it was sent to Kew about 1850 by Messrs. Jackson of Kingston, but had previously flowered with Messrs. Loddiges, for it was noticed in Paxton's "Magazine of Botany" in 1840. It is a very distinct form, with long narrow dark green leaves, and slightly nodding racemes 6 to 7 inches long of small closely placed creamy white flowers, which in their mode of arrangement are suggestive of *Dendrochilum glumaceum*. The spurs are comparatively short, and with a well-marked yellow tinge, which gives a peculiar appearance to the inflorescence.

An interesting plant is *A. distichum* owing to the peculiar form and arrangement of the leaves, and the diminutiveness of the plant. It affords a very striking contrast compared with *A. sesquipedale* both in the size of the flowers and general appearance. While the latter has the largest flowers in the genus and order and is of bold habit, *A. distichum* possesses unusually small flowers, certainly among the smallest of the order; and the short stems in tufts, with closely imbricated dark green leaves, still further add to its distinctiveness. In the habit of the plant there is little to suggest affinity with the *Angræcums* to casual observation, but there is a family likeness in the small white spurred flowers, which are produced from the axils of the leaves. However, by some authorities, for instance by Reichenbach, I understand that it has been considered sufficiently distinct to be assigned to another genus—namely, *Aeranthus*, but the older name is still retained in the chief collections, the other, *Aeranthus distichus*, being simply given as a synonym. The plant is found growing on the bark of trees in the neighbourhood of Sierra Leone, whence it was first imported by Messrs. Loddiges about 1835; so that it is an old inhabitant of our gardens, though by no means well known, perhaps owing to its being more curious than beautiful, though the neatness of the plant will always ensure it some admirers.—C.

EUCCHARIS AND THE MITE.

AN article on the above subject by "M. D." in the Journal for October 24th, page 349, reminded me of a mental promise I had made to furnish the Editor with the details of a rather dearly bought experiment, and which, I think, will materially strengthen "M. D.'s" conclusion. We had a dozen 10-inch pots which for years were the picture of health; the leaves were large and of a beautiful dark green; the pots also were full of bulbs and roots, as they had not been potted for six years. Do what we would, however, we could not induce them to throw up a number of flower spikes at one time, but only a few from each pot, and this at no definite time. They were grown in the stove with other plants, and when no young leaves were visible they were removed to a cool house and supplied with just sufficient water to preserve their leaves; but this and various other means used to induce them to flower freely signally failed to do so.

Under these circumstances we felt the plants were occupying valuable space without giving us adequate returns; and that being a state of things we never intend to tolerate longer than we are

obliged to, we decided to see what three months out of doors would do for them. Accordingly in July, 1887, we placed them out where they got a good deal of sun. In a few days they began giving unmistakeable signs of not being in their right element, and only the remembrance of their past behaviour would have induced us to leave them to their fate. When we removed them to the stove in September there were very few leaves left on them, and these were of a sickly hue. Our hopes of flowers were small, and we were not deceived, for only here and there one appeared, and these very feeble. For sixteen months we did all we could think of to restore them to health short of repotting them, but we could get nothing from them but a few sickly leaves, which almost as quickly died away.

In January this year we turned them out of their pots, intending to either finish them off or restore them to health. More than half of the bulbs had vanished, and what remained were many of them reduced to mere outside scales, and the whole were covered more or less with very minute insects, especially in and round the base of the bulbs and under the top part of the scales. Through a small pocket lens the insects appeared about the size of a red spider; and having never seen anything like them before we concluded they must be the Eucharis mite. I had read several appalling accounts of these creatures, and therefore concluded there were little hopes of restoring the bulbs to health.

Practical knowledge is always a tempting bait for a gardener, and here was one worth biting at; hence, notwithstanding the deplorable condition of the bulbs, we decided to give them a trial, consoling ourselves that, if we failed to restore them to health, we may learn something of the mite. The bulbs were all soaked, there were no roots, in a strong solution of fir tree oil for an hour. They were then treated separately and all loose scales removed, and all decayed parts brushed out with a nail-brush, and whilst still wet covered with powdered charcoal. They were sorted into three sizes and potted in well drained 6-inch pots, placing from six to twelve bulbs in a pot, the compost consisting of two parts loam, one part each of leaf mould and sand, with a sprinkling of bone dust and soot. We plunged them in a bottom heat of 80° in a close propagating pit, and to our surprise at the end of three weeks they began pushing up leaves, and by the end of April the plants were in full health and vigour. At the present time the plants are perfect little specimens, the large dark green leaves fully demonstrating the healthy condition of both roots and bulbs.

Our only regret is that we did not send some bulbs to the Editor, so as to have had an authoritative report as to the nature of the insects. As it is, not being versed in entomology, we are not in a safe position to positively affirm that the insects were what is known as the Eucharis mite, but from what we have read and heard of it we have every reason to believe it was; and that being so, here is a plain proof that they are the result and not the cause of Eucharis decadence. Moreover, a sudden check, low temperature, and careless watering will quickly make a healthy plant fit food for this dreaded enemy.—J. H. N.

DARK ROSES.

THESE are always admired, but unfortunately some of the plants that produce them are shy in growing. I intend shortly planting some scores of dark Roses with the object of having them early. I want them to grow freely, indeed climb walls if possible, and flower profusely. I have not arranged all my varieties, and any reader who has found some little known sort of special use under the conditions suggested would oblige by forwarding their experience for publication.

ROSE GLOIRE DE DIJON.

One of the best known Roses, and if all the Roses grown could be counted it would probably top the list, as it is much esteemed by amateurs and cottagers, but for all that it might be still more generally cultivated. Indeed there is no home in the kingdom that can accommodate a Rose that should be without it, as its combined qualities excel all others. It is wonderfully free in growth, hardy in constitution never refuses to grow, and never dies prematurely. In fact the death of a Gloire de Dijon Rose may be regarded as quite as great a wonder as the death of a certain well known quadruped in the animal kingdom. It is the alpha and omega of Roses, blooming so early as April, and never ceasing until severe frost occurs. I am within sight of several young plants that have produced shoots 12 feet in length since they were planted in March last, and another huge plant not further away has

produced thousands of blooms this season, and scores are still striving to develop. The buds when in a young state are charming buttonhole or bouquet flowers, and further on the huge buff fragrant blossoms delight all who see them. It is as a wall plant that this Rose shines. When grown as a bush it has rarely an opportunity of fully developing its splendid qualities.—ROSARIAN.

ROSES IN WINTER.

LOOKING over the Rose article by "Northener," on page 383, I notice he says, "All outside flowers are over by the end of October." I hope mine are not. At the present time I have a splendid lot, some blooms fit for any exhibition in July. A friend asked me the other day how I managed to have such blooms at this season of the year. My reply was rather a jocular one, but to the point. With manure and brains, or, to put it in another form, I added, cultivation with this object in view. I have a standard of Madame Berard with about 100 buds on in all stages, and a Souvenir de la Malmaison with about the same quantity, besides many other varieties. With mild weather I hope to have many useful blooms yet.—J. HAM.

EVENTS OF THE WEEK.—The Shows still continue numerous. To-day (Thursday) the Putney, Teddington, and Diss Chrysanthemum Societies will hold their annual Exhibitions. On Friday, November 15th, there are shows at Leicester and Cheshunt; on the following Tuesday (November 19th) at Twickenham and Winchester; on Wednesday (November 20th) the Birmingham and Rugby Exhibitions take place, and on Thursday the National Chrysanthemum Society's Provincial Show will be held at Hull in conjunction with the local Society.

— WORCESTER'S NEW MAYOR.—The Corporation of Worcester have this year taken the very unusual step of inviting a gentleman who was not one of their body to accept the office of Mayor, their choice falling upon Mr. Richard Smith-Carington, head of the firm of Messrs. R. Smith & Co., whose famous nurseries and seed establishment at Worcester are known far and wide. The festival of the three choirs, which is an historic musical gathering in the west midlands, takes place next September at Worcester, and the knowledge that Mr. Smith-Carington had for many years been one of the leading supporters of this festival, and of the clerical charity associated with it, largely influenced the Corporation in making their choice, which was unanimous. A few minutes after his election as Mayor, Mr. Smith-Carington was appointed an Alderman of the city for a term of six years, and he also holds the offices of Justice of the Peace and Charity Trustee. His worship's acceptance of the mayoralty has afforded much satisfaction, not only to the Corporation, but to the citizens, by whom he is held in much respect. He resides in the picturesquely situated mansion of St. Cloud at Powick, which affords a magnificent view of the Malvern Hills and the lovely Severn Valley.

— MR. BLACKMORE AND HIS GARDENER.—At Sunbury on Monday Mr. Blackmore, the well-known novelist, prosecuted his head gardener, a man named Tooley, for having stolen about £5 worth of Pears, and a Teddington fruiterer, named Woodward, for having received the property, well knowing it to have been stolen. The latter removed the Pears in a cart from Tooley's cottage to his shop, where Mr. Blackmore identified them. Tooley pleaded guilty, and was committed for three months with hard labour. Mr. Lyon, who appeared for Woodward, pleaded that there had been no wrongful act on his client's part, but the prisoner was sent for trial.

— SUSSEX RAINFALL.—The rainfall at Cuckfield, Mid-Sussex, for October was 6.61 inches, an amount only exceeded on two occasions during the past ten years—viz., October, 1880, when it was 8.23 inches, and October, 1882, when 6.86 inches was registered. It is 2.95 inches above the average. The heaviest fall was 0.89 inch on the 19th, rain falling on twenty-five days. Highest temperature (not strictly shade) 66° on the 10th and 13th; lowest temperature, 32° on 13th; mean day temperature, 59.3°; mean night ditto, 40.2°; mean temperature, 49.7°, just the average. No frost sufficient to injure Dahlias yet, and they are still quite gay, and Runner Beans are also uninjured.—R. INGLIS.

— WE are informed that the warming and ventilating of the various offices and Committee rooms in connection with the new Church House, Westminster, have had special attention bestowed upon them. This branch of the work having been executed by Messrs. J. WEEKS AND CO., King's Road, Chelsea, on the new and improved system which they have recently introduced, and which has given great satisfaction at the New Buildings, Eton College, and the numerous buildings to which it has been applied.

— *CYPRIPEDIUM SPICERIANUM*.—This charming Lady's Slipper is a striking object just now in one of the warm houses at the Birmingham Botanical Gardens, several splendid forms of this plant being now in full bloom. It is a compact small growing species with bright coloured flowers. Mr. Latham has raised most of these plants from seed, and although there is a slight variation in colour in some, the individuality of the species is preserved, and the plant is easily cultivated. It is truly a little gem, and should be in every collection.

— *EUCHARISES*.—The remarks of "A Londoner" (p. 398) anent the above subject calls for little comment beyond answering the question whether I believe in spontaneous generation. One does not necessarily require to be a believer in this theory to write the remarks which bring forth the query. That insects are generated in some plants more than others is a well-known fact, and my observations lead me to believe that certain conditions of plant life are more favourable for the growth of the invisible germs than others. When a plant is in a weak state from any unnatural cause, such as over-watering, this condition is much more suitable for their growth into insect life than when through proper management it retains its normal vigour. Many instances could be cited in proof of this, but it is quite unnecessary to bring forward any others than those already before the readers of the Journal. The two cases referred to in my previous communication occurred under my own notice, so that I can vouch for their authenticity, and the plants of *E. candida* afford similar evidence. From the concluding sentence of "A Londoner's" letter there seems to be a feeling abroad that I place light value on Mr. Pettigrew's ability as a gardener. Now, although I differ from his aquatic system of nursing baby *Eucharis*—to use "A Londoner's" term—from what I have heard and read about the Castle Gardens at Cardiff they must be under excellent management, and I yet hope to sail across and see them when my ship comes in.—M. D.

— *RESTING EUCHARISES*.—In Messrs. Roberts Brothers' great establishment for growing flowers for market at East Grinstead what may be fairly regarded as one of the finest collection of *Eucharises* in the kingdom may be seen. There are several large houses filled with plants, of which there must be some thousands, and they are remarkable for their vigour and floriferousness. "Do you rest them periodically?" was a question put to Mr. Roberts. "No," was his reply, with a shake of the head; "I should be very sorry." They are always moist, always growing, always flowering, and repotted about once in three years. They appear to be managed very much on Mr. Pettigrew's system, and it is impossible to imagine plants in a more satisfactory condition.—A LONDONER.

— *PEACH CULTURE IN THE OPEN AIR*.—I do not think this is practised very zealously. I have heard many say Peaches would not succeed in the open, but the attempts to produce them were not remarkable, and I do not know of a single instance where the matter was gone into thoroughly that it did not prove a success. In our case I do not consider the attention is special, yet we have been gathering Peaches constantly from the open walls since the middle of July, when that excellent early variety, Rivers' Alexandra, gave us our first fruits. This was followed by Hale's Early, then came Dr. Hogg, both good open air varieties. Barrington was fine during the first half of October, and Sea Eagle has not been long gathered. A supply of Peaches from the open walls for a period of four months is worth trying for, and I urge on all who never attempted their culture in the open to give them a trial, while those who never went into their culture heartily might profit by renewing it. Two points are absolutely essential in their treatment—one being thorough drainage for the trees to ensure their health, and the other efficient protection of the blossom from the time it expands until the fruit are formed.—SOUTH WALES.

— *DISEASED POTATOES* are generally regarded as so utterly worthless that they merit no treatment, but so long as they do not become pulpy they are valuable for pigs, and for this purpose alone they pay for attention. In some seasons we have thrown our small and

diseased Potatoes into a large heap, and in a week or two afterwards they were only a decayed mass; but this year we spread them out in a thin layer in an out-of-the-way corner under the trees, with the result that they are keeping some weeks longer than formerly, and the bulk of them will give a return in feeding.—M.

— *THE HALL AND FRASER FUND*.—Mr. Fred Horsman writes:—"I am pleased to inform you that the subscription up to date towards this Fund is upwards of £363. This week's list includes £10 from G. C. Raphael, Esq.; £10 from H. Greenfield, Esq.; and £5 5s. from Jas. Buchanan, Esq. If you will kindly ask the gardeners to contribute their mites it will enable us to soon close the list." Mr. Horsman's address is Hollybrook, Colechester, where subscriptions may be sent.

— *HENRY JACOBY AS A WINTER FLOWERING PELARGONIUM*.—This variety is well known as one of the most valuable in the flower garden in summer, but it is equally floriferous and showy if grown in 6-inch pots for conservatory decoration in winter. Some plants of it propagated last May, grown in the open in pots and never allowed to bloom until now, are opening many huge trusses, while many more are appearing. From past and present experience of all the *Pelargoniums* we have tried for winter flowering this one is the best.

— *MEDLARS* are a heavy crop. We only gather them when there is danger of their being injured by frost, and they are often on our trees in November. When taken in, we spread them out in a cool shed, and allow them to remain there until they become soft, when some are used for dessert, but the bulk are converted into a delicious jelly.

— *JUDGING VEGETABLES AT THE LATE EDINBURGH SHOW*.—"North Countryman" writes: "Vegetables always create much interest at Edinburgh, especially amongst professionals, and the exhibits in this section on a show day are judged (unofficially) hundreds of times over; but although I have attended these shows for many years, I have never been more puzzled to follow the judges than I was at the recent Show. Extreme size or coarseness were the only features I could see that they had recognised. The largest Onions irrespective of quality were first. Large dibble-formed Cucumbers were preferred to those of a compact type with little or no neck. In the leading collection of vegetables the same Cucumbers were prominent as one dish, another was composed of wrinkled Carrots, badly matched, that would not have gained a fourth prize in a Carrot class. A third dish was two Vegetable Marrows, mottled in character and of no recognised type, and a fourth dish was equally unsuitable for a gentleman's table, being two monster Cabbages of the Winningstadt form, and these were four of the dishes in the collection of twelve sorts that won the Veitch Memorial medal on the first occasion of its being offered for vegetables in Scotland."

— *BULLRUSHES FOR WINTER DECORATION*.—What is more pleasing for artistic decoration of vases and rooms in winter than Bullrushes? Few have an opportunity of seeing them growing naturally in their swampy bomes, and this is probably why they are so much valued artificially, but in many cases they are too late in being cut, and they are not long in becoming fluffy in the heads, and falling to pieces after being introduced to warm rooms. To avoid this they should always be cut before November, or a little before they become ripe, then the heads barden and remain intact for many months.

— *MICHAELMAS DAISIES*.—Even hardy flowers become scarce under the climatal conditions of October and November, and the majority of plants that were formerly bright assume a worn-out aspect, but that is the season when Michaelmas Daisies appear in their best form, and a collection of them is most valuable. The habit of all the varieties is good, the flowers varied in size and colour, although of the same form, and, cut or uncut, they charm all who come in contact with them. They should be grown in every garden.—PRACTITIONER.

— IT has been generally supposed that the *MANGO WEEVIL* infests the pulp of the fruit, but in a letter read at a recent meeting of the Committee of the Agri-Horticultural Society of Madras from Mr. C. I. Denton, forwarding specimens of Mangoes, called by the Canarese the Bee Mango, he states that the peculiarity of the fruit is that the stone contains a bee existing on the kernel. Specimens of the insect were forwarded by the Madras Agri-Horticultural Society to Mr. Coates of the Indian Museum, who identified them as *Cryptorhynchus magnifera*, the Mango weevil, whose normal habitation is in the pulp of the fruit, and not within the stone. The fruit sent to the Society was carefully examined, and the pulp was, in every case, free from the insect, which was only discovered when the stones from which the pulp had been removed were broken open.

— AN interesting paper on Japanese lacquer, read lately by Mr. R. Hitchcock before the Chemical Society of Washington, has been printed in the Proceedings of the United States National Museum. Japanese lacquer is the product of a tree, the *RHUS VERNICIFERA*, D.C., which grows throughout the main island of Japan. It attains a large size, the trunks sometimes measuring a metre in diameter. It is said the tree will live for forty years, but only comparatively young trees are valued for the production of lacquer. Having yielded for several years they are cut down, the lacquer extracted from the branches, and young trees take their places. Having given an account of the chemical composition of lacquer, and described the uses to which it is applied, Mr. Hitchcock urges that it should receive more attention than has hitherto been devoted to it by manufacturers in America. "It gives a surface to wood," he says, "much harder than our best copal varnish, without brittleness. It takes a polish not to be excelled, which lasts for centuries, as we may see in the old treasures of Japan. It is proof against boiling water, alcohol, and, indeed, it seems to be insoluble in every agent known. It is the best possible application for laboratory tables. I have a set of photographer's developing trays that have been in use for more than a year, and I find them excellent and cheap. In

heteroecism were adduced, and some problems suggested for the consideration of members of the Society. The Ustilagineæ were then shortly referred to, and *Ustilago segetum*, the corn-smut, given as a familiar example. The paper was illustrated by diagrams, specimens and the sections shown under the microscope.

CAREX VARIEGATA

ONE of the most graceful plants in the group of those suitable for table decoration, exhibited by Messrs. Veitch & Sons, Chelsea, at the meeting of the Royal Horticultural Society on October 22nd was that depicted in the woodcut (fig. 54). It is a variegated form of a species that has not yet been determined, as flowers have not been produced at present, but it has received the appropriate provisional name of *variegata*. The leaves are very narrow and slender throughout their entire length, most elegantly recurving and drooping, green with a pure white central stripe, that is shown in the drawing very clearly, as it is much reduced. It is difficult to imagine any plant better fitted for table decoration than this, and it will be a useful companion for the lighter *Crotons* and *Dracænas*.

FIG. 54.—*CAREX VARIEGATA*.

Japan it is used for many household articles." Unfortunately, lacquer poisoning from the fresh material is a serious danger. According to Rein, the poison is a volatile acid, and Mr. Hitchcock suggests that it might be removed by a heat that would leave the lacquer uninjured.

— AT the last meeting of the ANDERSONIAN NATURALISTS' SOCIETY of Glasgow, amongst the papers read was one by Mr. R. Turner Vice-President, on the "Uredineæ and Ustilagineæ." He explained the relations of these microscopic Fungi to other plants, and their position in the vegetable kingdom. They are all parasitic upon some living plant, and consist of two essential elements—spores and mycelium. The spores are very diverse, the mycelium very similar. The same mycelium gives rise to several different kinds of spores, each of these being formerly regarded as a different genus. The production of cluster-cups and of the spermatia, with their so-called spermatia, was described. It was shown that these spermatia have been by no means established as equivalent to pollen in function. As an example of heteroecism, the life history of *Puccinia graminis* was traced: first, the æcidiospore stage on the Barberry, then the rust on Wheat, succeeded by mildew, and finally, the germination of the teleutospores and the production again of æcidium on Barberry. Many other instances of

CHRYSANTHEMUM SHOWS.

NATIONAL CHRYSANTHEMUM SOCIETY, WESTMINSTER
AQUARIUM.—NOV. 12TH AND 13TH.

AS was expected, owing to the earliness of the season, the date fixed for the above Show proved fully too late, and numbers of intending exhibitors who had entered for the leading classes had to withdraw at the last moment. The competition was in consequence not quite so keen as usual, but the quality of the cut blooms was generally good. The groups and specimen plants were excellent, the display of vegetables, fruit, and sundries most extensive.

CUT BLOOMS.

The principal class was for forty-eight blooms, twenty-four incurved and twenty-four Japanese, restricted to *Chrysanthemum* and *Horticultural Societies*. The Wimbledon and District Royal Horticultural and Cottage Gardeners' Society, represented by Mr. C. Gibson, were first with a good collection, comprising the following varieties:—Japanese, back row: Edwin Molyneux, Sunflower, Mrs. J. Wright, Val d'Andorre, Fair Maid of Guernsey, Belle Paule, Carew Underwood, and Middle. Lacroix. Middle row: Lady Lawrence, Mons. Brunet, Ralph Brocklebank, M^{me}. Audiguier, Meg Merrilies, Boule d'Or, Album Pimbratium, and Charlie Sharman. Front row: L'Adorable, Mrs. H.

Wellam, Japonais, Pelican, Grandiflorum, Mdme. J. Laing, Jeanne Délaux, and Sarah Owen. Incurved, back row: Queen of England, Golden Empress (2), Empress of India (2), Golden Queen (2), and Lord Alcester. Middle row: Princess of Wales, Nil Desperandum, Miss M. A. Haggas (2), Violet Tomlin (2), Queen of England, Lord Wolseley, and Lord Alcester. Front row: Hero of Stoke Newington, Mr. Brunlees, Princess Teck, John Salter, Princess Beatrice, Barbara, Jeanne d'Arc, and Golden Eagle. The Cranbrook and Weald of Kent Society, represented by Mr. J. Doughty, were a very close second, and could have been but few points in the rear, the blooms being very fresh and good. The Hull and East Riding Society, represented by six growers, were third.

Incurved.—Forty-eight varieties were best shown by Mr. R. Adams, gardener to G. R. Hudson, Esq., Frogmore Hall, Hertford, who had an even and fresh display with no specially good blooms. The varieties were as follows:—Back row: Queen of England (3), Lord Alcester (3), Prince Alfred, Empress of India (3), Golden Empress, Bronze Queen of England (2), Alfred Salter, Golden Queen (2). Middle row: Miss M. A. Haggas (3), Princess of Wales (2), Golden Queen, John Salter (3), Alfred Salter (2), Violet Tomlin, Golden Empress, Lord Wolseley, Cherub, and Golden Empress. Front row: Mrs. Shipman, Refulgens (2), Princess Teck (2), Prince Alfred (2), Princess Beatrice, Barbara, Mrs. Heale (2), Mr. Brunlees, Lord Eversley, Cherub, Nonpareil, and Mrs. Norman Davis. Mr. G. Inglefield, gardener to Sir W. Kelk, Bart., Tedworth House, Marlborough, was second, but though some of his blooms were much finer than the first prize lot, notably the Queens, they were very uneven, some being quite commonplace. There appeared to be no other exhibitor. Mr. M. Sullivan, gardener to D. B. Chapman, Esq., Downshire House, Roehampton, won with twenty-four, a fresh, neat, even lot in perfect condition, though somewhat small. He was followed by E. Sanderson, Esq., Willesden, whose flowers were somewhat too small. Mr. W. Thomas, gardener to W. Marshall, Esq., Taunton, was third with larger but rough blooms. There were three exhibitors of twelve varieties (prizes given by Messrs. Jensen & Co.). Mr. A. J. Salter, gardener to T. B. Haywood, Esq., Reigate, won with a very neat lot of medium size; Mr. Thomas being second; and Mr. King, gardener to W. MacFarlane, Esq., Rickmansworth, third, both of these having larger, but coarse flowers. In another class for twelve Messrs. Hill, gardener to F. D. Brockman, Esq., Hythe; W. Collin, gardener to J. W. Carlisle, Esq., Hertford; and E. Santy, Esq., Ealing, received the awards, there being several other exhibitors.

Japanese.—These were shown very extensively, and formed a very fine display. In the chief class (forty-eight blooms) Mr. C. Cox, gardener to J. Trotter, Esq., Hertford, won, but with a very uneven lot. The varieties were as follows:—Back row: Madame Audiguier, Meg Merrilies, Boule d'Or, Stanstead White (2), W. G. Drover (2), Avalanche (2), E. Molyneux (2), Lady Lawrence, Duchess of Albany, Bouquet Fait, and Triomphe de la rue des Châlets. Middle row: Jeanne Délaux (2), Triomphe de la rue des Châlets, Elaine, Baronne de Prailly, Carew Underwood (2), Sunflower (2), Lady Lawrence, Ralph Brocklebank (2), Mons. Tarin, Mrs. Wheeler, Meg Merrilies, and Madame Audiguier. Front row: Baronne de Prailly, Val d'Andorre, Thunberg (2), Marguerite Marrouch (2), Mons. Astorg, Mr. J. Laing, Japonais (2), Mdle. Lacroix, L'Adorable, Album Fimbriatum, Sarah Owen, Duchess of Albany, and Mdle. B. Pigny. Mr. W. Packman, gardener to C. E. Shea, Esq., Foot's Cray, was second; and Mr. R. Adams third with moderate lots. There were several exhibitors of twenty-four blooms. Mr. W. Thomas won with a somewhat uneven stand, the best being Meg Merrilies, Madame Baco, Triomphe de la rue des Châlets, F. Marrouch, and Ralph Brocklebank. Mr. C. J. Salter was second with smaller but fresh flowers, and Mr. Inglefield third. Mr. W. Thomas again won with twelve blooms for Messrs. Jensen's prizes with a capital lot of flowers, amongst which Avalanche, Thunberg, Mrs. J. Laing, and Meg Merrilies were conspicuously fine. Mr. G. King was a moderate second, and Mr. Burnett, gardener to Mrs. Henton, Uxbridge, third. In another class for twelve Mr. Hill was first with a capital lot; E. Santy, Esq., second, and Mr. C. Lane, gardener to E. H. Coles, Esq., Caterham, third. Mr. Bettesworth, gardener to R. Ewing, Esq., Cheshunt, had a capital stand of Avalanche in the class for six White Japanese; Mr. D. Hill being second, and Mr. W. Thomas third with the same variety. The last named won with six of any colour, an admirable stand of Ralph Brocklebank; Mr. Calvert, gardener to J. H. Houblon, Esq., Bishops Stortford second with Boule d'Or, and Mr. J. Moon third with Mr. H. Cannell.

Reflexed (twelve) were well shown by Mr. Collin, the blooms being all in good condition. The varieties were—King of Crimson, White Christine, Cloth of Gold, Peach Christine (2), Golden Christine (2), Cullingfordi (2), Phidias, Dr. Sharpe, and Pink Christine. Mr. M. Russell, gardener to Dr. Lewis, Henfield, was second with smaller but neat blooms, and Mr. D. Hill third. In two other stands, Amy Furze (not admissible) was shown. Japanese reflexed (twelve) were best shown by Mr. W. Packman, the varieties being Val d'Andorre (2), L'Adorable (2), Mr. J. Laing, Maiden's Blush, J. Délaux (2), Madlle. Paule Dutour, La Triomphante, Elaine, and Criterion; Mr. J. Moon, gardener to the Misses Arkwright, Harlow, following. Mr. M. Sullivan won with large Anemones, a fairly good lot, comprising Mr. Pethers, Lady Margaret (good), Emperor, Nelson, Sabine, George Sand, J. Thorpe, jun., Acquisition, La Marguerite, Fleur de Marie, Mrs. Taylor, and Nouvelle Alvéole. E. C. Jukes, Esq., Winchmore Hill, was a very

creditable second, and Mr. Russell third. Mr. Sullivan again won with Japanese Anemones, good examples of Jeanne Marty (3), Souvenir de Madame Blandinières, Madame Cabrol (2), Ratapail, Madame Clos, Fabian de Médiana, Marjolaine, Madame Ghys, and Madame Berthe Pigny. There appeared to be no other in competition. Mr. G. French, gardener to Dr. Stanley Adams, Palmer's Green, won with Anemone Pompons, a neat and very pleasing stand, the varieties being Regulus, Marguerite de Coi, Rose Marguerite, Briolis, Madame Montels, Mr. Astie, Marie Stuart, Queen of Anemones, Antonius, Miss Nightingale, Perle, and Madame Sentir. Mr. W. G. Gilbert, gardener to B. Foster, Esq., Guist, Norfolk, was a fair second, and Mr. Chadwick, gardener to E. M. Nelson, Esq., Ealing, third.

The classes for bouquets, wreaths, epergnes, &c., produced a very beautiful display. For a table with bouquets, wreaths, sprays, button-holes, &c., Messrs. Perkin & Sons, Coventry, won with a most chaste and beautiful arrangement. Mr. G. Newman, Broadway, Bromley, second, and Mr. W. Gordon, 41, Duke Street, St. James', third, extra prizes going to Mr. W. Brown, Richmond, and Madame Josephine, 4, Lower Grosvenor Place, Belgravia. Mr. J. B. Crane, Archway Road, Highgate, was placed first for a bouquet, Mr. Ings, gardener to Sir S. Wells, Hampstead, second, and Mr. W. Gearing, Sevenoaks, third.

GROUPS.

Undoubtedly the finest in the Exhibition, and perhaps one of the best seen this year, was that arranged by Messrs. Laing & Sons, Forest Hill. The plants ranged from 9 or 10 feet high at the back to about 2½ feet in front, sloping smoothly down, the plants healthy, the blooms good, and the colours admirably blended. The first prize was deservedly awarded to it. Mr. J. Townsend, Providence Nursery, Putney, exhibited very creditably also, his plants being well clothed with fine foliage and the blooms good, but with almost too great a preponderance of light shades. He was placed second, and the remaining prize went to Mr. G. Stevens, St. John's Nursery, Putney, the yellow, bronze, and orange shades in his group requiring more relief; one other was shown. Messrs. Laing also won with a smaller group restricted to Japanese varieties, Mr. W. Holmes, Frampton Park Nurseries, Hackney, following.

SPECIMEN PLANTS.

Owing to these being arranged for general effect several of the classes were split up and placed in different portions of the building, and it was somewhat difficult to get the whole of the awards. Mr. Harris, Southampton, won with nine trained specimens, large, healthy, profusely bloomed plants; Mr. J. Watson, gardener to D. Martineau, Esq., Clapham Park, second; and Mr. Easey, gardener to J. W. Jones, Esq., Highbury New Park, third, an extra prize going to Mr. W. Wesker. Mr. Davey, gardener to E. C. Paine, Esq., Stamford Hill, won with four standards, the second prize falling to Mr. Wraight, gardener to W. Johnson, Esq., Upper Clapton, and the third to Mr. W. Clarke, gardener to J. H. Lile, Esq., Brixton Hill. The latter, who showed successfully at Brixton last week, won with six large flowering varieties, Messrs. W. Davey and Wraight following; an extra prize was awarded to Mr. Easey. Mr. Harris won with four plants in not larger than 12-inch pots, Mr. W. Clarke being second; and with trained Pompons Mr. Weston was successful, the second prize going to Mr. J. Mackenzie.

MISCELLANEOUS EXHIBITS.

Space does not allow of more than a passing reference to the fruit and vegetables, which formed a very fine display in the galleries, and in St. Stephen's Hall; nor to the miscellaneous exhibits. But it may be noted that the latter included a beautiful collection of Carnations from Mr. Jennings, gardener to L. de Rothschild, Esq., Ascott, Leighton Buzzard; and a splendid display of Chrysanthemums from Messrs. Cannell and Sons, Swanley, who had stands of Japanese, Incurved, Pompons, Anemone flowered and singles in bunches, these presenting a most beautiful effect, especially the last-named. Mr. Cannell also exhibited fine stands of Zonal Pelargoniums. A small collection of Primulas was shown by Mr. C. Titmus, Leytonstone, and a pleasing display of Cyclamens by Mr. J. May, Twickenham. Messrs. Pitcher and Manda, Short Hills, U.S.A., exhibited a collection of seedling Chrysanthemums, and a stand of Mrs. Alpheus Hardy in capital condition. Horticultural buildings and appliances were exhibited by Messrs. Foster & Pearson, Beeston; Messrs. Peel & Sons, Wood Green; and G. Hayward & Co., Brockley. Messrs. Deards & Co. exhibited their Victoria system of dry glazing, and also heating apparatus; Messrs. E. & F. Newton exhibited their patent system of fitting and glazing; and Messrs. Page & Co. exhibited their patent lead glazing. Garden sundries were shown by several firms. Messrs. Corry, Soper, Fowler & Co. exhibited a stand of Standen's manure; and Messrs. Brangwin & Co. had barrows and garden seats, also heating apparatus. Fibrous peat and other sundries came from Messrs. Wood & Son, and H. G. Smyth; Chrysanthemum cuttings in fertilising moss from Messrs. Beale & Co., New Southgate; ichthemie guano from Mr. W. Colchester of Ipswich; and Mr. J. George, Putney, exhibited a variety of horticultural sundries and manures.

The Floral Committee held a meeting at 12:30 P.M., Mr. R. Ballantine in the chair, when there were present Messrs. E. Sanderson, G. Gordon, L. Castle, R. Dean, G. Addison, C. Gibson, G. Stevens, J. Wright, H. Cannell, and R. Owen. The exhibits were numerous, Mr. R. Owen alone having over 100 blooms, representing many new varieties (silver medal). Certificates were awarded for the following:—

Miss Margaret (W. Boyce).—A large Anemone, with pink ray florets, and pale yellow disc, very handsome.

John Doughty (J. Doughty).—A beautiful incurved sport from Queen of England, of a soft rosy salmon tint, delicate and charming.

Mrs. Alpheus Hardy (Pitcher & Manda).—A Japanese already described.

Lady Dorothy (H. Cannell).—A rosy buff sport from Hero of Stoke Newington.

Madame Alfred Carrière (R. Owen).—A Japanese reflexed with white, narrow, recurving florets, neat and good.

Mrs. S. Colman (R. Owen).—A sport from Princess of Wales, bronzy with a purple tint.

Mrs. Judge Benedict (R. Owen).—A large Anemone, blush ray, pale yellow disk, very high and well formed.

Lune Fleuri (R. Owen).—A Pompon, with small globular dark golden blooms.

Madame Baco (Bettesworth).—A Japanese, large rosy pink blooms, the florets toothed at the points.

Willy (W. Holmes).—An incurved sport from Captivation, yellowish bronze, a delicate tint and good bloom.

CRYSTAL PALACE.—NOVEMBER 8TH AND 9TH.

IT was expected that the earlier shows this season would have the advantage, and it has proved to be the case so far, as those held during the past week were exceptionally good in the number and quality of the exhibits. The date fixed for the annual Show at Sydenham was well judged, it suited a large number of competitors admirably, and the substantial cash prizes induced many to come from a considerable distance. Altogether a very representative Show was provided, the competition in some of the classes being unusually keen. For instance, it is doubtful if fourteen stands of forty-eight blooms have ever been seen at one show and in one class before. This alone would render the Palace celebration of the centenary remarkable. Then, too, in some of the smaller classes, notably for twelve Japanese, there were twenty entries, and others in proportion, so that the greater part of the available space in the north nave was occupied with tables devoted to eut blooms. The effects of the season were visible, it is true, even in some of the best stands, and it was evident that the majority had experienced difficulty in preserving their blooms, or in making up the stands entirely with fresh samples. In some of the freshest there were evident signs of roughness, more especially in the incurved, which in two or three cases were also weak, more particularly in the class for eighteen varieties. But the most notable feature in the Exhibition was the numbers of new exhibitors that entered, and took the honours from older and more experienced cultivators. This occurred in several classes, but their successes were well deserved, and it indicates that the culture of the Chrysanthemum for exhibition has by no means yet reached the limit of its popularity.

Mr. W. G. Head arranged the exhibits to the best advantage, the eut blooms on tables, with small Palms and other plants in the centre and between them, the specimen plants at the end, and the groups at the sides. Beyond the competing Chrysanthemums there were, however, numerous groups of plants grown in the Palace gardens that displayed their attractions in various parts of the building. Primulas were also fairly shown, and the competition in the special classes for Potatoes brought numerous exhibits that occupied a large space.

Cut Blooms.—The chief class in this section was provided for forty-eight blooms, twenty-four incurved and twenty-four Japanese, not less than eighteen varieties of each, or two of one variety, the prizes being £10, £7, £5, and £3. As already stated there were fourteen exhibitors, all showing well, but their positions were pretty clearly defined. Premier honours went to Mr. G. Inglefield, gardener to Sir J. W. Kelk, Bart., Tedworth Gardens, Marlborough, who had excellent stands of blooms, comprising the following varieties:—*Incurved.*—Back row: Golden Empress, Empress of India, Lord Alcester, Empress of India, Lord Alcester, Queen of England, Golden Empress, and Golden Queen. Middle row: Queen of England, Jeanne d'Arc, Princess of Wales, Miss M. H. Haggas, Jeanne d'Arc, Alfred Salter, Lord Wolseley, and Miss Mary Morgan. Front row: Nil Desperandum, Princess Beatrice, Refulgens, Mrs. Heale, Hero of Stoke Newington, Mrs. Shipman, Lady Hardinge, and Barbara. *Japanese.*—Back row: M. J. M. Pigny, Madame Baco, E. Molyneux, Boule d'Or, M. J. M. Pigny, Madame C. Audiguier, E. Molyneux, and W. and G. Drover. Middle row: Ralph Brocklebank, G. Daniels, Mrs. J. Wright, Baronne de Prailly, Mdlle. Lacroix, Japonais, Meg Merrilies, and Carew Underwood. Front row: Madame Laing, Bertha Flight, J. Délaux, Avalanche, Balmoreau, Blanche Neige (like Mdlle. B. Pigny), Madame Baco, and Avalanche. The incurved were of good depth and substance, even, fresh, and admirable in all points; the Japanese also were well developed and richly coloured. Mr. Peter Blair, gardener to the Duke of Sutherland, Trentham, Stoke-on-Trent, was a good second, his Japanese being very fine, especially Belle Paule, Val d'Andorre, J. Délaux, Boule d'Or, and Sunflower. The incurved were not quite so even, but were notable for the breadth of their florets. Mr. J. Doughty, gardener to Mrs. Tomlin, Angley Park, Cranbrook, was third, his incurved being very even, fresh, and good, but a trifle small and flat. The Japanese also were very even and bright, but not large.

There were five exhibitors of eighteen incurved varieties, but none was of remarkable quality. Mr. J. Horsefield, gardener to Lord Heytesbury, Heytesbury, Wilts, was placed first with rather small and weak blooms. Mr. P. Blair was a close second, and Mr. M. Sullivan, gardener to D. B. Chapman, Esq., Downshire House, Roehampton, third. Twelve stands of twelve incurved blooms

were shown by Mr. W. Collins, gardener to J. W. Carlisle, Esq., The Gardens, Ponsbourne Park, Hertford, being first with Lord Alcester, Queen of England, Mrs. N. Davis, White Empress, Mrs. Heale, Alfred Salter, Queen of the Isles, Princess of Wales, Cherub, Lord Wolseley, and Jeanne d'Arc. Mr. C. Ritchings, gardener to W. Lindsey, Esq., Brandries, Beddington, was second; and Mr. J. Wilkins, gardener to J. M. Pearson, Esq., The Grange, Kingston Hill, third. Ten exhibitors staged in the six incurved class, one variety, Mr. Blair winning the premier position with grand examples of Queen of England. Mr. Ritchings followed with Golden Empress of India; and Mr. J. Hewett, gardener to H. R. Macheson, Esq., Hillside House, Hythe, was third.

Japanese were capitally shown in three classes. With eighteen varieties Mr. J. Blackburne, gardener to John Scott, jun., Esq., Elmstead Grange, Chislehurst, took the lead with handsome substantial blooms of the following:—Back row: Boule d'Or, Avalanche (small), A. Molyneux (large), Stanstead White (very fine), Val d'Andorre, and Etoile de Lyon. Middle row:—J. Délaux, M. Bernard, Sunflower, Madame J. Laing, Ralph Brocklebank, and Sarah Owen. Front row: Meg Merrilies, Criterion, Japonais, Gloriosum, Carew Underwood, and Maiden's Blush. Of the ten other exhibitors Mr. C. Cox, gardener to J. Trotter, Esq., Hertford, was second for fine bright blooms; and Mr. T. Skimmer, gardener to J. Aird, Esq., M.P., East Sutton Park, Staplehurst, third, showing good blooms, but not so even. Amongst twenty stands of twelve Japanese Mr. Slogrove, gardener to Mrs. Crawford, Gatton, Reigate, was first with fresh even blooms of Val d'Andorre, Sunflower, E. Molyneux, Maiden's Blush, Mdlle. Lacroix, Mr. H. Cannell, J. Délaux, and Avalanche. Mr. W. Collins was placed second, his back row blooms being very fine. Mr. A. G. Hookings, gardener to S. W. Graystone, Esq., Hurst Side, West Moulsey, secured the third place, good blooms of Sunflower, Ralph Brocklebank, and Golden Dragon being conspicuous. Ten stands of six blooms (one variety) were shown, Mr. P. Blair leading with grand deep blooms of Avalanche. Mr. H. Harker, gardener to H. Shindler, Esq., Oakwood Lodge, Epsom, was second with Japonais, very handsome; and Mr. Shoesmith third with Avalanche. Capital stands of Ralph Brocklebank, Triomphe de la rue des Châlets, Meg Merrilies, and Etoile de Lyon were also shown, the first named variety being exceedingly fine.

With twelve reflexed, not less than eight varieties, Mr. Collins won first honours for deep blooms of the following arranged in this order, Golden Christine, Cullingfordi, Golden Christine, and Cullingfordi. Middle row: Cloth of Gold, Pink Christine, King of Crimson, Peach Christine. Front row: White Christine, King of the Crimson, Peach Christine, and Dr. Sharpe. Mr. Hookings was second with even blooms, and Mr. Felgate, gardener to the Duchess of Wellington, Burhill, Walton-on-Thames, was third for creditable blooms. A class was provided for twelve Anemone flowered, not less than eight varieties (Japanese Anemones excluded), and Mr. M. Sullivan was accorded the first prize for handsome blooms of the unnamed varieties. Back row: Emperor, Lady Margaret, Nelson, and Sabine. Middle row: Sabine, Nelson, Gluck, and Mrs. Taylor, pale purple, of good shape. Front row: La Marguerite, Acquisition, Georges Sands, and J. Thorpe, jun. Mr. A. Combes, gardener to the Earl of Dudley, Himby Hall, Dudley, Staffordshire, was a close second, with even blooms, and Mr. Collins followed. Four beautiful stands of twelve Pommpons were shown, Mr. G. Duncan, gardener to C. J. Lucas, Esq., Warnham Court, Horsham, being first with excellent examples of Marabout, Comte de Morny, Prince of Orange, Prince Victor, Rosea perfecta, Rosinante, Black Douglas, Mdlle. E. Dordan, Mdlle. Marthe, Pygmalion, M. Hoste, and Charles Dickens. Mr. C. Gibson was second, and Mr. E. Chadwick third. Mr. Duncan was also first with twelve Pompon Anemones, admirable blooms of La Marguerite, Mr. Astic, Antonius, Madame Sentir, and Mdlle. Montels. Mr. Gibson was second and Mr. G. Gilbert third. Japanese Anemones were well shown by Mr. M. Sullivan, who was first, followed by Messrs. Combes and Gibson. Only one stand of twelve singles was shown by Mr. Chadwick, who took the first prize for neat, graceful blooms of Miss Mary Anderson, Lady Churchill, Canary, Magenta King, Scarlet Gem, Mrs. W. Woods and others.

The best groups were those with which Messrs. J. Laing & Sons, Forest Hill, secured first prizes in the classes for Japanese and incurved varieties respectively. Both these were very effectively arranged, contained well grown plants of the best varieties and bearing fine blooms. The amateurs' groups were not so tasteful in arrangement as might be desired, in fact in one or two cases they were finished in a careless and clumsy manner. Specimen plants were well represented, the chief prizes being awarded to Messrs. W. Clark, Weston, Cherry, Westcar, G. A. Cooper, and J. McKenzie. The special prizes offered by Messrs. J. Carter & Co., Sutton & Sons, and C. Fidler for collections of Potatoes brought numerous exhibitors, the tubers staged being in most cases of considerable merit.

First-class certificates were awarded to Mr. W. Packman for Chrysanthemums Sunflower, Etoile de Lyon, Stanstead White; Mr. T. S. Ware for Chrysanthemum Mr. Alpheus Hardy; Mr. G. Stevens for new Chrysanthemum Alice Stevens; Messrs. J. Laing & Sons for Chrysanthemums L'Automne, Miss Haggas, Stanstead Surprise, Stanstead White, Etoile de Lyon, and Sunflower; Mr. C. W. Howard for Potato Robert Fenn; Mr. R. F. Jameson for Name Card Holder; Messrs. R. Beale & Co., commended for leaf culture of Chrysanthemums.

BRIXTON.—NOVEMBER 5TH AND 6TH.

THE Brixton, Streatham, and Clapham Chrysanthemum Society held their thirtieth annual Exhibition in the lecture hall attached to the

Congregational Church on Streatham Hill on the above dates. The Show was of about the usual dimensions, and although not large was of an extremely attractive character, a suitable structure and excellence of arrangement combining to provide one of the most pleasing displays of any show of a similar character in the neighbourhood of the metropolis. It is not restricted solely to Chrysanthemums, but foliage and table plants, as well as fruit and vegetables, are asked for, and, interspersed with the flowering plants, lent an agreeable contrast. The blooms exhibited were, on the whole, of fair average quality, Japanese being largely and well represented. In the principal class (for twenty-four), Mr. Mursell, gardener to Mrs. Burton, Leigham Court Road, Streatham, had some capital examples, including Ralph Brocklebank, Stanstead White, La Boule d'Or, and Etoile de Lyon. Messrs. Howe, gardener to H. Tate, Esq., Clapham Common, and Sadler, gardener to Mrs. Lambert, Leigham Court Road, also showed well. Mr. Howe won with twelves, a very fair lot; Mr. Mursell was a close second; and Messrs. Brown, gardener to G. R. Peerless, Esq., Park Hill House, Clapham, and Guyett, gardener to T. Gabriel, Esq., Leigham Court Road, equal third.

Mr. Howe showed incurved extremely well, and won in both classes, the blooms being neat, fresh and well coloured, and Mr. Parrott (gardener to H. Russell, Esq., Clapham Common), Mr. Sadler, Mr. W. Hill (gardener to G. W. Ryder, Esq., Streatham Hill) and A. Upton, 127, Chatham Road, Wandsworth Common, took the minor prizes. A capital stand of large Anemone flowered took the first prize for Mr. Fulbrook (gardener to B. Baker, Esq., Palace Road). The flowers were large and well finished; this was one of the best stands in the Show. Other prizewinners in the cut flower class were Mr. Gibbons, gardener to Lady Pollock, Thurlow, Clapham; Swain, gardener to E. Jones, Esq., Atkins Road, Clapham Park; S. Ashley, gardener to J. Staines, Esq., Leigham Court Road, and C. Livermore, gardener to F. Webb, Esq., Christchurch Road. A first-class certificate was awarded to Mr. Mursell for a well formed bloom of Etoile de Lyon.

Specimen plants were healthy and well flowered. Mr. W. Clarke, gardener to J. H. Lile, Esq., Brixton Hill, won with six, these including a capital Dr. Sharpe. Mr. Cherry, gardener to Mrs. Gabriel, Streatham, was second with smaller plants; and Mr. J. Weston, gardener to D. Martineau, Esq., Clapham Park, was third. Mr. Clarke also won with three—Dr. Sharpe, Etoile, and Mrs. Dixon. Specimen Japanese were well shown by Mr. Weston in response to special prizes offered by T. Gabriel, Esq. He was easily first; Messrs. Clarke and Cherry equal second. Pyramidal Pompons were not so good, Mr. Clarke's first prize plants not being well flowered. Mr. Livermore (second) had larger plants with the same fault; and Mr. Cherry (third), smaller specimens. Flat trained specimens were well shown by Messrs. Clarke and Weston; and Mr. R. Clarke, gardener to W. Griffiths, Esq., Palace Road, had good specimens.

Ferns were exhibited in good condition by Mr. A. Gidner, Mr. W. Hill, and Mr. H. Wright, and Orchids by Mr. J. Jones, gardener to N. N. Sherwood, Esq., Streatham Hill; Mursell; Wainford, gardener to W. Dent, Esq., Streatham Hill; Ranson, gardener to J. T. Gabriel, Esq., Hill, and Guyett. Several of the exhibitors named also showed well in other classes, but lack of space forbids further reference.

KENT COUNTY.—N V. 6TH AND 7TH.

ONE of the best provincial exhibitions of the season was held at the Rink, Blackheath, on the dates above named. The schedule consisted of about fifty classes, and in all there was very keen competition, many of the most noted growers of the day contesting with each other for the prizes. The larger classes for cut blooms contained nine, ten, and eleven collections, while the display throughout was notable for the absence of inferior exhibits. A few years since a noted horticulturist, while writing on the Liverpool exhibits of Chrysanthemums, said that Mrs. G. Rundle would not be found in a collection of twenty-four distinct in the north, and such is the state of things now in the south, for in this excellent Show the only moderate exhibit was the third prize collection of twelve blooms of Mrs. G. Rundle. The Kent County executive are to be praised for the varied schedule and the substantial prizes offered.

In the open classes for thirty-six blooms, eighteen incurved and eighteen Japanese, distinct, there were nine competitors, all the collections being above ordinary merit. First honours were awarded to Mr. Sullivan, gardener to D. B. Chapman, Esq., Downshire House, Roehampton, for large solid blooms, consisting of Japanese—Avalanche, Mrs. F. Jameson, E. Molyneux, Mons. Bernard, Stanstead Surprise, Sunflower, Etoile de Lyon, Japonais, J. Délaux, Mdle. Lacroix, Marsa, Boule d'Or (very fine), Mrs. J. Wright, Criterion, Dormillion, Mdle. Blanche Pigny, Val d'Andorre, and Marguerite Marrouh. Incurved—Queen of England, Violet Tomlin, Lord Wolseley, Jeanne d'Arc (very good), Emily Dale, John Salter, Mrs. Heale, Alfred Salter, Mr. Bunn, Princess Beatrice, Lord Alcester, Prince Alfred, Miss Haggas (the best flower of this lovely variety in the Show, and there were several good flowers shown), Nil Desperandum, Princess of Wales (fine), Lady Harding, Empress of India, and Mr. Brunlees. Mr. Doughty, gardener to Mrs. Tomlin, Angley Park, Cranbrook, was a very good second, his best blooms being Empress of India, C. Gibson, Jeanne d'Arc, Refulgens, Princess Teck, Queen of England, Ralph Brocklebank, Jeanne Délaux, Belle Paule, and Madame Baco; all good. Mr. W. Packman, gardener to C. E. Shea, Esq., The Elms, Foot's Cray, was placed third for a very even collection.

In the class for twelve incurved, distinct, Mr. Mease, gardener to A. Tate, Esq., Downside, Leatherhead, gained the premier position for a

very neat collection of Empress of India, Miss Haggas (good), Queen of England, Lord Alcester, Lord Wolseley, Jeanne d'Arc, J. Salter, Hero of Stoke Newington, Golden Empress, Refulgens, Violet Tomlin, and Princess of Teck. Mr. Blackburne, gardener to John Scott, Esq., Chislehurst; and Mr. James Hudd, gardener to W. F. Prior, Esq., Blackheath Park, were second and third respectively. Eleven competitors staged twelve Japanese distinct, first honours falling to Mr. J. Blackburne for massive blooms of E. Molyneux, Ralph Brocklebank, J. Délaux, Stanstead White, Val d'Andorre, Avalanche, Etoile de Lyon, Boule d'Or, Mons. Bernard, Mrs. J. Laing, and Criterion. Mr. J. Mitchell, gardener to Mrs. Arbutnot, Bexley, was placed second, his Marsa, Jeanne Délaux, and Madame Baco were particularly noticeable. Mr. Leadbetter, gardener to A. G. Hubbuck, Esq., Chislehurst, was a very good third. For twelve reflexed, not less than eight varieties nor more than two blooms of any variety, Mr. Mease outdistanced all others with Golden Christine (two), Dr. Sharp, Cloth of Gold, King of Crimson (two), Lilac Christine (two), Cullingfordi, Chevalier Domage, and Mrs. Forsyth (two). Messrs. Leadbetter and Tomalin shared the second and third honours. An interesting class was twelve Japanese or large-flowered Anemones, distinct. Mr. Mitchell, who secured the first prize, staged amongst others Gluck, Sabine, Empress, Nelson, and Fabian de Mediana. Mr. Sullivan was a very good second, and Mr. F. Moore, gardener to W. S. Pickersell, Esq., Bexley, third; all exhibiting well.

Classes were provided for six Japanese white, and the same number of coloured. For the first there were eight collections staged. Mr. Hudd took premier position with Mdle. Lacroix; Mr. H. Smith, Rochester, second with Avalanche; and Mr. Pannell, gardener to Macdonald Smith, Esq., Catherham, third with Mdle. Lacroix. In the coloured class a stand of Sunflower from Mr. Moore was well ahead, the colour and substance were all that could be desired. Mr. Briscoe Ironsides was placed second with large blooms of Edwin Molyneux and W. Packman with Ralph Brocklebank. For six incurved one variety, Queen of England from Mr. Blackburne, Prince Alfred from Mr. Briscoe Ironsides, and Mr. Bunn from Mr. Pannell were placed first, second, and third respectively.

In the gardeners' classes for eighteen Japanese, Mr. Blackburne was again to the front with fine blooms of Etoile de Lyon, Sarah Owen, Maiden's Bush, Val d'Andorre, Carew Underwood, Ralph Brocklebank, Stanstead White, Mrs. J. Laing, Gloriosum, E. Molyneux, Sunflower, Madame C. Audiguer, Meg Merrilies, Madame Baco, Criterion, Boule d'Or, Avalanche, and Jeanne Délaux. Messrs. Packman and Mease shared the other awards, in the order of their names. There were nine collections of twelve incurved, and Mr. T. Skinner, gardener to J. Aird, Esq., M.P., Staplehurst, was placed first with massive blooms of Queen of England, Alfred Salter, Prince of Wales, Golden Empress, Jeanne d'Arc, Violet Tomlin, Empress of India, Empress Eugénie, Mrs. Shipman, Mr. Bunn, Barbara, and Lady Hardinge. The second prize fell to Mr. Blackburne, who ran very close; and the third to Mr. Barnes, gardener to A. Bovall, Esq., Grove Park. For twelve Japanese there were ten collections staged, and to Mr. Blick, gardener to M. Smith, Esq., The Warren, Hayes, the first honours fell for Sunflower, Japonais, Jeanne Délaux, Etoile de Lyon, Avalanche, Criterion, Val d'Andorre, Thunberg, Carew Underwood, E. Molyneux, Fair Maid of Guernsey, and Mr. H. Cannell. Messrs. Tomalin and Barnes were placed second and third respectively. Mr. Mease, Mr. Mullins, and Mr. Pannell were placed in the order of their names in the awards for six incurved, distinct. The first prize collection consisted of Lord Alcester, Empress of India, Queen of England, Jeanne d'Arc, Miss Haggas, and Princess Teck.

There was also special prizes offered for twenty-four blooms, eight incurved, eight Japanese, eight reflexed, all distinct. There were nine competitors, Mr. Blackburne taking first place with large developed blooms of Etoile de Lyon, Meg Merrilies, Mons. Bernard, Boule d'Or, E. Molyneux, Stanstead White, Val d'Andorre, and Ralph Brocklebank, Mrs. Shipman, Lord Alcester, Empress of India, Golden Empress, Queen of England, Golden Queen of England, Alfred Salter, Prince Alfred, Chevalier Domage, White Christine, Cullingfordi, Magdeleine Tezier, King of the Crimson, Peach Christine, Bronze Christine, and Amy Furze. Messrs. Mitchell and Packman were placed second and third respectively. There were several other classes set apart for amateurs, who exhibited remarkably well. Mr. Briscoe Ironsides and Dr. Walker from Wimbledon were prominent in nearly all the classes, and their blooms were equal in merit to the rest of the Show.

Groups were very good, and the sides of the large building were fairly crowded with them. Trained plants were not plentiful, but those in competition were all that could be desired. Hand bouquets and cpergnes were tastefully arranged, whilst Primulas, Heaths, and table plants helped to tone down the gorgeous colours of so many cut blooms. Altogether it was a noble display and well arranged.

PORTSMOUTH.—NOVEMBER 6TH, 7TH, AND 8TH.

THE fifth annual Exhibition of this flourishing Society was held in the spacious Drill Hall, Alfred Road, and proved in every respect a decided success. A remarkable advance in the quality of the exhibits was manifest all through, and it is not too much to say that this Exhibition ranks as one of the most important in the kingdom. The cause of this is not far to seek. A special policy by the executive is maintained of offering liberal prizes, and plenty of them. This is a sure way of procuring a good show, and the low prices of admission enable the people flock to the building in extraordinary numbers. No society is better managed than this one. Mr. F. Power, the courteous Hon. Secretary,

is as deservedly popular with exhibitors as he is with the general public, and he is ably assisted by his assistant Mr. B. Miller. The arrangement of the exhibits was as usual in the hands of Mr. J. C. Collins, Milton House Gardens, Waterloo-ville. Hence the good order prevailing everywhere. We are glad to hear the Show was as great a success financially as it was in an horticultural point of view, and it was particularly gratifying to note the extent and excellence of the amateurs' exhibits, some of the dockyard workmen staging blooms of a very high order of merit. We now pass to notice the chief classes in this great and good Show.

Cut Blooms.—These constituted the chief attraction, 2100 large blooms being staged, besides Pompons and singles, which were excellent, while many of the incurved blooms were of immense size and superior in quality. The principal class was that for thirty-six distinct varieties, half incurved and the remainder Japanese. A silver cup, value £25, and £6 in cash was offered as first prize, second £5, third £2 10s., fourth £1. It may be mentioned that Messrs. W. & G. Drover, nurserymen, Fareham, last year won this cup for the first time. It was necessary to secure the same position again to enable them to become the possessors of this trophy, therefore much interest was centred in this class. After a spirited competition and a close scrutiny by the Judges, Messrs. Drover won by the superior weight and finish of the incurved blooms; the Japanese too combined large size with freshness, all being neatly arranged. The winning stand contained the following varieties:—Incurved, back row: Queen of England, Golden Empress, Lord Alcester (very fine, the premier incurved bloom of the Show), Alfred Salter, rich, Empress of India, and Golden Queen of England. Middle row: Princess Teck, Empress Eugénie, weak, Princess of Wales, deep, Mrs. Norman Davis, Novelty, and Lord Wolseley. Front row: Eve, Charles Gibson, good, Nil Desperandum, Jeanne d'Arc, Barbara, and Mrs. W. Shipman, Japanese, back row: Boule d'Or, rich, M. J. M. Pigny, Carew Underwood, very fine, Frederick Marrouch, Mez Merrilies, and Mons. Bernard, finely coloured. Middle row: Baronne de Prailly, Ralph Brocklebank, Mdme. C. Audiguier, Edwin Molyneux, grand, Etoile de Lyon, splendid, and Gloriosum. Front row: Mrs. J. Wright, Jeanne Délaux, Mrs. H. Wellam, Mdme. Baco, Avalanche, and Fimbriatum. Mr. W. Neville, gardener to F. W. Flight, Esq., Cornstiles, Twyford, Winchester, was a good second, his stand of Japanese containing many excellent blooms. Stanstead White was of extraordinary proportions, and in excellent form, this being awarded premier honours as the best Japanese bloom in the Show; Album Fimbriatum, Ralph Brocklebank, L'Or du Japon, and Stanstead Surprise. The incurved blooms were rather weak in the back row as compared with the same row in the first prize stand. Mr. G. Trinder, gardener to Sir Henry St. John Mildmay, Dogmersfield Park, Winchfield, was third, showing excellent Japanese. There were seven competitors in the class.

For twenty-four distinct varieties, half to be incurved and half Japanese, the first prize was £5, and three others in due proportion. Seven collections were staged. Mr. G. Inglefield, gardener to Sir J. Kelk, Bart., Tedworth, Marlborough, was a good first, the blooms being large and well coloured, but too many whites were placed together in the Japanese stand. Incurved, back row: Empress of India, large; Golden Empress, Queen of England, and Lord Alcester. Middle row: Jeanne d'Arc, Prince Alfred, Miss M. A. Haggas, and Alfred Salter. Front row: Jardin des Plantes, Nil Desperandum, Refulgens, and Princess Beatrice. Japanese, back row: Ralph Brocklebank, M. J. M. Pigny, Boule d'Or, and Madame C. Audiguier, large. Middle row: Carew Underwood, Bertha Flight, Soleil Levant, and Edwin Molyneux, rich. Front row: Mrs. J. Wright, Madame Baco, full; Avalanche, and Mdme. Lacroix. Mr. G. Edwards, gardener to the Dowager Countess Enniskillen, Witley Heights, Witley, Surrey, was a good second, the Japanese being of excellent quality.

Five competitors staged in the class for twelve incurved blooms, the best coming from Mr. G. Inglefield, who had large well-finished examples of Empress of India, Lord Alcester, Queen of England, Golden Empress, Miss M. A. Haggas, Prince Alfred, Jeanne d'Arc, Alfred Salter, Princess Beatrice, Jardin des Plantes, Refulgens, and Barbara. Mr. A. Abrahams, gardener to T. H. Wilson, Esq., Hazelholt, Bishop's Waltham, was a close second, having smaller but slightly better finished blooms. For twelve Japanese, distinct, nine entered, the first prize falling to Mr. Trinder for a heavy stand, comprising Boule d'Or, Mrs. F. Thompson, Edwin Molyneux, Avalanche, Madame C. Audiguier, Sunflower, Meg Merrilies, Carew Underwood, Mrs. C. Wheeler, Madame Laing, Japonais, and Ralph Brocklebank. Mr. Inglefield followed with smaller blooms. There was a brisk competition for the prizes offered for twelve reflexed in not less than eight varieties, ten competing, highest honours falling to Mr. G. Russell, gardener to Dr. C. Lewis, Henfield, Sussex, Pink Christine (two), Golden Christine (two), Dr. Sharp, Cullingfordi (two), Cloth of Gold, Pink Christine, Distinction, King of Crimson, and Mrs. Forsythe. Mr. Woodfine, gardener to Captain Boyd, Emsworth House, Havant, was an exceedingly close second with large blooms. Messrs. Drover easily took leading honours with splendid examples in the class for twelve Show Anemones in not less than six varieties—Lady Margaret, Souvenir de L'Ardenne (two), Messrs. W. and G. Drover (two), a richly coloured dark rose variety; Laing's Anemone (two), Gluck (two), Miss Annie Lowe, and Nouvelle Alvéole (two). Mr. C. Penford, gardener to Sir F. Fitzwygram, Bart., Leigh Park, Havant, was a good second. The last-named exhibitors stood in the same order of merit in the class for twelve Japanese Anemones in six varieties, the former having good blooms of Mdme. Cabrol (two), Fabian de Mediana (two), Margaret Villageoise (two), Margouline

(two), Minnie Chate (two), and Jean Marty (two). Japanese blooms, six of any one variety, were represented by nine competitors, making a good display. Mr. N. Molyneux, gardener to J. Carpenter Garnier, Esq., Rooksbury Park, Wickham, Fareham, secured the premier award with Avalanche, large and solid; Mr. G. Hawkins, gardener to E. Laphorne, Esq., Gosport, being second with same variety in good condition. For six of any incurved variety Mr. Molyneux again took first honours with large firm blooms, superbly finished, of Golden Queen of England; second Mr. H. Adams, gardener to T. S. Edgecombe, Esq., Hinton House, Southsea.

Pompons made a good display in bunches of three blooms each. The first prize was worthily taken by Mr. Russell, amongst ten others, with a good lot, the most noteworthy being Marabout, Comte de Morny, Golden Marabout, Mrs. Holmes, and Rubrum Perfectum neatly arranged. Mr. G. Hawkins second. For twelve bunches of fimbriated, three blooms to a bunch, not less than four varieties, the first prize was awarded to Mr. Hatch, Superintendent Victoria Park, Portsmouth, for a neat lot, Chardonnet, Croesus, and Massange being the most noteworthy. Mr. H. Adams second. A beautiful class. Single varieties, twelve bunches of three blooms each, were best shown by Mr. J. Agate, nurseryman, Havant, his flowers being large, well coloured and neatly arranged, Admiral Sir T. Symonds, Mary Anderson, and Jane were the best, Mr. H. Adams following with smaller flowers. Six entries.

A maiden class for six blooms, provided for those who have never taken a prize for Chrysanthemums, produced sixteen entries. Mr. N. Molyneux was distinctly ahead with large finely finished blooms of Empress of India, Golden Empress, and Queen of England. Messrs. W. Wood & Son, Wood Green, London, offered a silver cup value 5 guineas for three blooms of Japanese and the same of incurved, for which sixteen growers competed. Mr. Inglefield easily secured the trophy with blooms of Golden Empress and Empress of India fully 5½ inches in diameter and 4½ inches deep, with extra large petals, he also staging well Sunflower and Avalanche. Mr. Trinder was second. Mr. W. Colchester, Ipswich, also offered a silver cup of the same value and under the same conditions as in the preceding class. Here again Mr. Inglefield secured the Judge's award with immense blooms, Messrs. W. & G. Drover being a close second. Many classes were provided for exhibitors residing in Portsea Island only, and substantial prizes were offered. The competition was keen and the produce excellent. Similar remarks apply to the amateur classes, but space cannot be found for details.

Plants.—These were quite equal, and in most classes superior in merit to those of former years. The principal class was for eight trained specimens, four incurved or reflexed, and the remainder Japanese. The handsome prizes of £10, £6, £4, £2, produced four competitors. Mr. F. Wakeford, gardener to Mr. G. Harris, Aldermoor, Shirley, was accorded premier honours for plants 3 to 4 feet in diameter, profusely flowered, neatly trained, and well selected. Comet, very full; Mons. Astorg, exceedingly handsome; La Nympe, with fully 200 expanded blooms, and a rather weak Mrs. Dixon. Mr. E. Wills, gardener to Mrs. Pearce, Bassett, Southampton, was a close second with larger plants but not so freely flowered. Mr. Penford third. Six competed with a group of Chrysanthemums arranged in a space of 50 square feet. Mr. Hatch out-distanced his rivals easily with an excellent group of dwarf well-foliaged plants carrying substantial blooms neatly, and yet not stiffly, arranged. Mr. Gale, gardener to Mr. G. Cooke, Langton House, Gosport, was second. Several groups were spoiled by a forest of obtrusive stakes. For twelve plants in pots not exceeding 9 inches in diameter, the number of flowers on each ranging from six to twelve, with upright trained stems 3 to 4 feet high, Mr. Hatch easily secured the leading position. Mr. J. Burridge, London Road, Landport, was second, also showing well. Mr. Hatch followed up his previous success in the class for eight Pompons, distinct, freely flowered and trained, ranging from 2 to 3 feet in diameter. The best single specimen was Peter the Great, with upwards of sixty expanded blooms of good quality from Mr. Wills.

Miscellaneous plants such as those best suited for table decoration, also double and single Primulas, were staged numerous and well, the principal prizetakers being Messrs. Wills, Mr. A. Carpenter, Fratton Road, Landport, and Mr. C. A. Kingswell (gardener to W. E. Gordon, Esq., H.M. Dockyard, Portsmouth). A feature of the Exhibition was the epergnes dressed with berries and autumn foliage, and others with Chrysanthemums, flowers, and Ferns. There was a spirited competition. Mrs. Conway obtained the coveted position in both classes with neatly arranged stands.

Fruit.—Of this it can only be said there was a great and good display. Mr. T. Hall, gardener to Mr. S. Montague, M.P., South Stoneham House; Mr. G. Inglefield; Mr. E. Molyneux, gardener to W. H. Myers, Esq., Swanmore House, Bishops Waltham; Mr. G. Busby, gardener to F. Willan, Esq., Thornhill Park, Bitterne; Mr. J. Chalk, gardener to G. Read, Esq., Salisbury; and Mr. Penford were the most successful exhibitors in the various Grape classes. In the class for fifty dishes of Apples and Pears Messrs. G. Bunyard & Co., the Nurseries, Maidstone, experienced no difficulty in securing the first prize of £5, Mr. J. Watkins, Pomona Nursery, Withington, Hereford, being second. Other classes for Apples and Pears were well filled.

There were numerous exhibits of vegetables, the quality being of the best. Mr. Inglefield secured leading honours in collections of eight and five distinct varieties, with capital produce arranged in an attractive manner. A new class for the best collection of Fungi was made, and created considerable interest. Mr. J. J. Moor, 25, Upper Arundel Street

Landport, secured the first prize with a large and varied assortment, tastefully arranged.

STAINES AND EGHAM.—NOVEMBER 7TH.

DURING the eight years this Society has been in existence it has made considerable advance in the merit of its shows, and that held last Thursday would compare very favourably with any that had preceded it, especially in the quality of the exhibits. The Town Hall at Staines is a commodious building, and all available space was suitably occupied, without crowding, yet leaving room for visitors to inspect the various attractions. The groups were assigned a position near the walls, the tables of cut blooms and small plants being placed in the centre, and the vegetables near the entrance. All the arrangements were most satisfactory, the courteous Secretary, Mr. T. J. Rawlings, being greatly assisted by several members of the Committee, and though the entries were numerous, everything was prepared for the judges promptly.

Cut blooms were excellently shown in most of the principal classes, and in two or three cases the exhibits were so nearly equal in merit that their positions could only be determined by careful pointing. In the class for twenty-four incurved blooms, not less than eighteen varieties, there were five competitors, all staging good examples, but the best were those from Mr. C. Page, gardener to H. P. Leschallas, Esq., Bagshot, who won the first prize. These were admirable, solid, clean, well-developed blooms, well showing the form and finish expected in the incurved. The varieties were as follows—Back row: Golden Empress of India, Empress of India, Alfred Salter, Queen of England, Alfred Salter, Lord Alcester, Prince Alfred, and Emily Dale. Middle row: Mrs. Heale, Mr. Brunlees, Princess of Wales, Lord Wolseley, Golden Empress, Nil Desperandum, Jeanne d'Arc, and Mr. Brunlees. Front row: Barbara, Violet Tomlin, Mabel Ward, Empress Eugénie, Princess Beatrice, Miss M. A. Haggas, Lady Carey, and Eve. The second place was taken by Mr. J. Tomlin, gardener to T. Ashby, Esq., Sunninghill, and his blooms were but a few points behind the first. All were fresh, well-grown specimens, but some were a little wanting in substance compared with the first. The varieties were—Back row: Golden Empress, Prince Alfred, Empress of India, Lord Wolseley, Lord Alcester, Queen of England, Lord Wolseley, and Lord Alcester. Middle row: Alfred Salter, Queen of England, Violet Tomlin, Golden Empress, Mr. Brunlees, Princess of Teck, Queen of England, and Prince Alfred. Front row: Jeanne d'Arc, John Salter, White Venus, Refulgens, Empress Eugénie, Barbara, Lady Hardinge, and Mrs. Shipman. Mr. H. Tomlinson, gardener to F. Ricardo, Esq., Old Windsor, was third with good blooms a trifle rough.

Japanese blooms were capitally shown, particularly in the class for twenty-four in not less than eighteen varieties, six competitors staging collections of remarkably even merit. Mr. C. Page was again first, showing excellent specimens of the under-mentioned varieties, arranged in this order:—Back row: Madame C. Audiguier, Avalanche, Japonais, Madame J. Laing, E. Molyneux, Fair Maid of Guernsey, Ralph Brocklebank, and Stanstead Surprise. Middle row: Sarah Owen, J. Délaux, Meg Merrilies, Val d'Andorre, Sunflower, Madame Baco, Madame B. Pigny, and Triomphe de la rue des Châlets. Front row: George Daniels, Thunberg, Roi des Japonais, Album fimbriatum, Marsa, Duchess of Albany, Balmoreau, and Golden Dragon. Mr. J. Tomlin followed again in this class also very closely, his blooms being fresh and even with the exception of three examples, that were each a point inferior to most of the others. The stand comprised the following:—Back row: Comte de Germiny, E. Molyneux, Madame C. Audiguier, Ralph Brocklebank, Japonais, Avalanche, E. Molyneux, and Meg Merrilies. Middle row: Val d'Andorre, Avalanche, Criterion, E. Molyneux, Boule d'Or, Madame Laing, Gloriosum, and Sarah Owen. Front row: Thunberg, Madame Laing, Sunflower, Belle Paule, Val d'Andorre, G. Daniels, Fimbriatum, and Fair Maid of Guernsey. Mr. F. Sturt, gardener to L. Cohen, Esq., Englefield Green, was a good third.

In the smaller classes there was also close competition. Mr. W. Orchard, gardener to J. C. Fraser, Esq., Thorpe, was successful in several classes. Messrs. F. Sturt, G. Collinge; J. Marcham, gardener to Miss Arnott, Englefield Green; W. Atherley, gardener to E. C. Haines, Esq., Staines; Ager, Bubb, Hutchings, Reddick, and Thatcher securing the chief prizes with praiseworthy exhibits.

For groups Mr. W. Orchard was first, having a collection comprising good quality blooms effectively arranged. Mr. Hutchings followed with dwarf plants, and Mr. Thatcher was third. The prizewinners for plants were Messrs. Reddick, Sturt, Thatcher, and Hutchings. Vegetables also were excellently represented. Apples, Pears, and Grapes were also staged in satisfactory condition, but these, like many others at this and similar shows, cannot, owing to the demands upon our space, be referred to in detail.

EAST GRINSTEAD.—NOVEMBER 7TH.

THE Chrysanthemum Society of this pleasant Sussex town is now merged in the Horticultural Society, of which G. Wyatt Truscott, Esq., is the active and much esteemed President. The Show to be noticed very briefly was held in the Public Hall, a commodious and well-appointed building that was erected in commemoration of Her Majesty's Jubilee, for purposes of instruction and recreation. The Exhibition was not large, but in the cut bloom department, and especially in the Japanese classes, very good indeed, competition being of the keenest possible character. It was hard to find a point of difference in several of the stands, and those exhibitors who were defeated were certainly not disgraced.

In the open class for twenty-four incurved blooms, distinct, four

collections were staged, the successful competitors being Mr. J. Heasman, gardener to Mrs. Oxley; Mr. L. Budworth, gardener to C. Hill, Esq.; Mr. J. Boland, gardener to Sir Edward Blount; and Mr. R. White, gardener to Mrs. Stenning, in the order named. The first prize stands contained the following varieties very well represented—Lord Wolseley, Empress of India, Lady Hardinge, Lord Alcester, Novelty, Prince Alfred, John Salter, Mrs. W. Shipman, Golden Beverley, Baron Beaufort, Bronze Queen, Alfred Salter, Golden Queen of England, Golden Empress, White Venus, Mr. Brunlees, Cherub, Mrs. G. Rundle, Mrs. Dixon, Antonelli, Princess Teck, and Guernsey Nugget. Several of the incurved blooms had lost their freshness, and were doubtless in much better condition a week before the Show.

The open class for twelve varieties of Japanese brought eight excellent stands, the first prize blooms of Mr. Budworth comprising fine examples of Thunberg, Maiden's Blush, Japonaise, E. Molyneux, Madame Lacroix, Mad. C. Audiguier, Comte de Germiny, Triomphe de la rue des Châlets, Bend Or, Jeanne Délaux, Meg Merrilies, and The Daimio, Messrs. Heasman and White followed very closely indeed, and secured the remaining prizes.

In the corresponding local class there were ten competitors, all staging well. Mr. White secured the chief prize with E. Molyneux, Mrs. J. Wright, Thunberg, M. J. Pigny, Mad. J. Laing, Jeanne Délaux, Mad. C. Audiguier, Belle Paule, R. Brocklebank, Madame Lacroix, Boule d'Or, and Japonaise, all in good condition, Messrs. Heasman and Friend being second and third respectively in a keenly contested class.

The best Japanese bloom in the Show was a very fine example of Avalanche, in a stand exhibited by Mr. F. Dunn, gardener to Sir Francis Wyatt Truscott, Oakleigh. Incurved, reflexed, and Anemone varieties were well staged in the local classes by Messrs. Smith, Roberts, Boland, Heasman, and other exhibitors.

Mr. F. Dunn was the only exhibitor of a group of plants. It was in every respect highly meritorious, and unanimously adjudged the first prize. The specimen plants were mostly trained upright for conservatory decoration, and were healthy and well flowered, Messrs. Boland, Dunn, and Harris, Marden and Dawe being the chief prizetakers. Mr. F. Bloodworth exhibited by far the best bouquet.

Mr. W. Prentice, gardener to R. Whitehead, Esq., Paddockhurst, secured the first prizes in all the fruit classes—Black and white Grapes, culinary and dessert Apples and Pears, with very fine blooms. Messrs. J. & A. Cheal staged an excellent collection of fruit not for competition. Great pressure on space precludes further reference to this creditable Show, which was arranged under the superintendence of the active Hon. Secretaries, Messrs. Jenks and F. W. Beck.

SALISBURY.—NOVEMBER 7TH AND 8TH.

THE Wilts Horticultural Society held its fourth annual Exhibition of Chrysanthemums, fruits, and flowers in the new county hall on the above dates, and although the entries were not quite so numerous as last year the Show was, nevertheless, a good one. Messrs. Keynes, Williams, and Co. contributed a large quantity of decorative plants in the way of Palms, Crotons, Ferns, well-flowered Primulas, and Chrysanthemums, which were arranged with good taste and telling effect.

Groups form quite a feature in the summer and autumn shows of this Society. Last year two challenge cups, value 10 guineas and 5 guineas respectively (the former being open to all, and the latter confined to exhibitors who do not employ a regular gardener), were offered for groups arranged in a semicircle not exceeding 10 feet in diameter, and 6 feet in the one class and 8 feet by 5 feet in the other, the cups to be won three times in succession before becoming the property of any competitor. In the large group class Mr. E. L. Brown, Portland House, Salisbury, was first with a capital arrangement, winning the 10-guinea cup for the second time. Mr. Curry, gardener to Colonel Pepper, Milford Hill, Salisbury, was a creditable second; and Mr. J. W. Lovibond, St. Anne Street, Salisbury, was third. With a group of miscellaneous plants Dr. F. W. Coates, Salisbury, was an excellent first with a very tasteful arrangement. Mr. John Curry was second; and Mr. W. H. Pearce, High Street, Salisbury, third. With a group of Chrysanthemums arranged for effect in a semicircle of 8 feet by 5 feet Mr. Charles Haskins, Poultry Cross, Salisbury, won the 5-guinea cup for the second time with well flowered plants tastefully arranged. Mr. Cripps, Salisbury, was a good second; and Mr. Frank Pearce an excellent third. Mr. E. L. Brown had the best four plants of Chrysanthemums; Mr. Haskins the second best; and Mr. Chalk, gardener to George Read, Esq., Westwood, Salisbury, the third best.

Cut Blooms.—In addition to several money prizes two challenge cups of the same value and under the same conditions as those indicated were offered in two classes for cut blooms. In the class for twenty-four blooms, to include not more than two of any one variety, Mr. H. W. Ward, gardener to the Earl of Radnor, Longford Castle, Salisbury, was first, winning the £10 cup for the second time with good solid stands of bright coloured Japanese, Avalanche, 5 inches deep and 6½ inches wide; Ralph Brocklebank, large and full; Grandiflorum, Duchess of Albany, and Japanese being of fine quality. The incurved blooms were of medium size, even, smooth in floret, and well finished, the best among them being Lord Alcester, John Salter, Miss M. A. Haggas, Barbara, and Jeanne d'Arc. Mr. T. Wilkinson, gardener to C. C. Tudway, Esq., The Cedars, Wells, was a good second. With a stand of eighteen blooms Mr. T. Annals, gardener to Challoner Shenton, Esq., Winchester, won the £5 5s. cup for the second time. His blooms were fresh, but not very large. Mr. H. Snook, Fratton, Portsmouth, was second, and Mr. George Smith, Wilton Road, Salisbury, was

third. In other classes the principal winners were Messrs. Ward, Chalk, H. Osman, gardener to T. Strong, Esq., Harefield, Romsey. Fruit was also well shown, and other exhibits were numerous, but we cannot refer to them now. Mr. W. H. Williams deserves credit for the able manner in which he conducted the arrangements.

ST. NEOTS.—NOVEMBER 11TH.

A CAPITAL show was held in the Corn Exchange, St. Neots, last Monday, being the sixth this Society has had, and it proved to be the best, for the competition was close in the principal classes, and the quality of the cut blooms in several of the stands was admirable. Classes were provided for cut blooms in all the sections, bouquets, buttonholes, baskets of flowers, groups of plants, specimens, fruit and vegetables. A series of classes was also appropriated to cottagers in which vegetables were excellently shown.

The special feature of the Exhibition, however, was the class for thirty-six Chrysanthemum blooms, eighteen incurved and eighteen Japanese in not less than twelve varieties each. Four prizes were offered, the first of £3 being in addition to a handsome challenge cup, value 7 guineas. This cup was offered on the condition that if it be won twice consecutively or three times altogether by the same exhibitor it should become his property. Last year it was won for the first time by Mr. R. Adams, gardener to G. B. Hudson, Esq., Frogmore Hall, Hertford, and the contest was therefore looked forward to with considerable interest. Six competitors staged collections, and though there was a good contest between the first and second, Mr. Adams was again successful, securing the cup with several points to spare. He well deserved his success, for the blooms are cut from a comparatively small collection of plants, and all must be well grown to admit of so many good blooms being staged. The varieties were as follows, arranged in the order named—Incurved, back row: Empress of India, Bronze Queen, Empress of India, Golden Empress, Queen of England, and Lord Wolseley. Middle row: Lord Alcester, Golden Queen, Alfred Salter, Queen of England, Lord Alcester and Alfred Salter. Front row: Violet Tomlin, Miss M. A. Haggas, Princess of Wales, John Salter (2), and Golden Empress. Japanese, back row: Baronne de Prailly, Avalanche, Japonais, Boule d'Or, Triomphe de la rue des Châlets, and Baronne de Prailly. Middle row: Triomphe de la rue des Châlets, Ralph Brocklebank, Madame C. Audiguier, Carew Underwood, Ralph Brocklebank, Avalanche. Front row: Mdlle. Lacroix, Madame Laing, Meg Merrilies, M. Freeman, Madame C. Audiguier and Mr. H. Cannell. All these were fine examples, the incurved deep and well developed, the Japanese large and richly coloured. Mr. R. Petfield, gardener to A. J. Thornhill, Esq., Diddington, was second, his Japanese blooms being about equal to the first, but he lost some points in the incurved, though all were meritorious in a season like this. Mr. J. Myers, gardener to the Earl of Sandwich, Hinchinbrook, was third with a fresh even collection, and Mr. F. M. Anthony, Leicester, fourth with fine Japanese blooms, but rather small incurved.

In other classes there were also some praiseworthy exhibits. Mr. Adams had the best twelve incurved, followed by Messrs. Petfield and Myers, the last two also being respectively first and second with twelve Japanese. Reflexed were shown by Messrs. Myers, Thomas, gardener to Lord Esmé Gordon, Paxton Park; and Mr. Thomas was first with twelve large Anemones. Specimen plants were not well shown, but there were several effective groups, Messrs. Myers, Redman, and Thomas securing the prizes in that order.

A room was specially devoted to bouquets, &c., Messrs. Myers and Beaumont winning the prizes with tasteful exhibits, perhaps a little too crowded, with bouquets of miscellaneous flowers. Messrs. Redman and Myers were placed first and second, the best baskets of Chrysanthemums coming from Messrs. Myers and Thomas. Buttonholes were tasteful and good, Mr. Thomas leading with three, comprising Violets, pink and white double Bouvardias and Tuberoses, Mr. Myers following with red and white Bouvardias, Rose buds and Violets, and Roman Hyacinths with Violets; but this exhibitor was first for table decorations with a charming arrangement. Collections of fruit, Apples, Pears, and vegetables were all shown in excellent condition.

The Secretary, Mr. Ratchelous, who is well known in the district, has aided greatly in the development of this Society, and has an energetic and a thoroughly interested coadjutor in Mr. Plum, who is one of the members of the Committee.

SURREY CHRYSANTHEMUM SOCIETY.—NOVEMBER 11TH AND 12TH.

THE Public Hall in Rye Lane, Peckham, was the scene of the above Society's sixth annual Exhibition, and the numerous groups of plants produced a fairly effective general display. As regards merit, however, there was very much to be desired, and the quality of the cut blooms was not of the character looked for at the present time.

The first prize group in Class 1 was arranged by Mr. W. Dickens, gardener to E. Biever, Esq., Champion Hill. The plants were in moderate condition, and some of the blooms fairly good, but the heavy red curtains on the windows of the hall prevented the colours being properly displayed, and should have been removed or drawn well back. Mr. F. B. Elson, gardener to — Peel, Esq., Loughborough Park, Brixton, was second with equally good materials, marred by overcrowding. The third prize lot was from Mr. Dominy, The Gardens, 23, Basset Road, Nunhead. Messrs. Snod, 29, Bellenden Road Peckham; W. J. Head, 28, Peckham Grove, S.E.; and C. J. Bennetts, 174, Milkwood Road,

Herne Hill, received other awards. Far the best group in the Show was arranged by Mr. Witty, Nunhead Cemetery, but it was not in competition, and Mr. Nix, Danby Street, Peckham, also had a small non-competing group. Of the specimen plants nothing need be said.

The cut blooms were very small and rough. Mr. T. Sadler, gardener to Mrs. Lambert, Streatham, was first with twelve incurved of a very modest character, Mr. Brunlees being perhaps the best bloom. Mr. D. Agate, gardener to Mrs. Walton, Woodlands, Peckham Rye, was second; and Mr. W. Dominy third. Mr. Sadler was a little stronger with Japanese, and again won, the flowers being small, but fresh and well coloured; Mr. Elson was second, and Mr. Agate third. Mr. Sadler's first prize lot of reflexed contained one or two good blooms, but he had no opponent. Mr. Dominy received a third prize for Anemone flowered. In the amateurs' classes the chief prizes fell to Mr. J. F. Vaughan, Mr. Head, Mr. W. S. Harper, Mr. J. B. Worley, and Mr. F. G. Morley. Mr. C. J. Bennetts was first with a bouquet of Chrysanthemums, Mr. H. A. Bultitude second, and Mr. H. Glasscoo third. The same exhibitors, amateur and professional, were successful in other classes. Mr. Springett is the Honorary Secretary of the Society.

KINGSTON-ON-THAMES.—NOVEMBER 12TH AND 13TH.

FOR the thirteenth time the Kingston and Surbiton Society, which has done so much in furtherance of high-class Chrysanthemum culture, has held its annual Show. Like others that have been held in the Drill Hall, made famous by noteworthy contests, the Exhibition was, on the whole, a very good one. There appeared to be a little falling off in groups and specimen plants, but the compensation was ample in the cut bloom classes. The competition was excellent, and the quality, especially of the Japanese and reflexed flowers, superior.

The chief interest naturally centred in the challenge vase class of forty-eight distinct varieties, half incurved and half Japanese. The Kingston eup or vase, the first of the great trophies in the Chrysanthemum world, must be won twice by the same exhibitor before he can become its possessor. The first eup was won by the late Mr. G. Harding, two others by Mr. E. Molyneux, the fourth by Mr. C. Gibson, and last year Mr. E. Coombs, gardener to W. Furze, Esq., Teddington, won the first chance for the fifth, and as he won again on this occasion by a few points only, the coveted trophy is secured.

The blooms in the winning stands were:—Incurved, back row: Empress of India, Alfred Salter, Lord Wolseley, Golden Empress of India, Emily Dale, Prince Alfred, Lord Alcester, Queen of England. Middle row: John Salter, Jeanne d'Are, Miss Haggas, Violet Tomlin, Princess of Wales, Mrs. Heale, Mr. Brunlees, Prince of Wales. Front row: Princess Beatrice, Barbara Baron Beust, Princess Teek, Mrs. Shipman, Lady Hardinge, Perle Précieuse, Mr. Bunn. Japanese, back row: Edwin Molyneux, Etoile de Lyon, Mad. C. Audiguier, Boule d'Or, Stanstead White, Japonaise, Ralph Brocklebank, Avalanche. Middle row: Belle Paule, Marsa, Sunflower, Mrs. J. Wright, Duchess of Albany, Comtesse de Beauregard, Condor, Mr. Elliott. Front row: Mrs. F. Jameson, Florence Percy, Val d'Andorre, Mad. J. Laing, Album Plenum, Gloriosum, Hamlet, George Daniels. Second, Mr. W. Mease, gardener to A. Tate, Esq., Downside, Leatherhead, with splendid Japanese. Third, Mr. C. Beckett, gardener to T. H. Bryant, Esq., Juniper Hill, Dorking. Fourth, Mr. G. Carpenter, gardener to Major Collis Brown, Broad Oaks, Byfleet. Seven collections were staged.

Substantial prizes were provided for twenty-four incurved varieties, in which five collections were staged. The blooms were somewhat rough, but competition close. The chief position was secured by Mr. E. Coombs. Second, Mr. G. Woodgate, gardener to the Lady Wolverton, Coombe Wood. Third, Mr. J. Thorn, gardener to A. Flood, Esq., The Bush, Walton.

The class for twelve incurved, distinct, contained five collections. First, Mr. R. Carote, gardener to J. P. Robinson, Esq., Brookleigh Esher, with Emily Dale, Empress of India, Queen of England, Lord Alcester, Princess Teek, John Salter, Guernsey Nugget, Barbara, Mr. Brunlees, Lady Hardinge, Jeanne d'Are, Mabel Ward. Second, Mr. C. Beckett. Third, Mr. J. Wilkins, gardener to J. M. Pearson, Esq., The Grange. Fourth, Mr. W. Davis, gardener to T. P. Chappell, Esq., Weir Bank, Teddington. In the class for six incurved varieties Mr. A. Folgate, gardener to the Duchess of Wellington, Burhill, Walton, was first, Mr. J. Quarterman second, and Mr. H. Hawkes third. The class for six incurved blooms of one variety invariably produces an imposing display. Mr. E. Coombs was placed first with compact blooms of Violet Tomlin; Mrs. Carpenter second with Golden Queen, large but loose; and Mr. Thorne, gardener to A. Flood, Esq., third with Empress of India.

Corresponding with the incurved were similar classes, and equally good prizes for Japanese varieties. The response was excellent. In the class for twenty-four varieties there were seven exhibitors, Mr. G. Holden, gardener to Mrs. G. W. Izod, The Lammas, Esher, winning first honours with splendid examples of Sarah Owen, Madame B. Rendatler, Sunflower, Madame John Laing, Val d'Andorre, Condor, La Triomphante, E. Molyneux, Charlie Sharman, Meg Merrilies, Criterion, F. A. Davis, Boule d'Or, Marguerite Marrouh, Ralph Brocklebank, Madame Baco, Mr. H. Wellam, Mons. Bernard, Mons. Tarin, Mdlle. Lacroix, Hamlet, Duchess of Albany, John Laing, Avalanche. Second, Mr. W. Mease; third, Mr. J. Thorne; fourth, Mr. C. Woodgate. The class for twelve blooms brought five exhibitors. First, Mr. C. Beckett, gardener to T. H. Bryant, Esq., Juniper Hill, Dorking; second, Mr. A. C. Hook-

ings, gardener to S. W. Graystone, Esq., Hurst Side, W. Mo'esev; third, Mr. R. Carotc, gardener to J. P. Robinson, Esq., Brookleigh, Esher; fourth, Mr. J. Wilkins. The varieties in the prize stand were:—George Daniels, J. Délaux, Madame Audiguier, Etoile de Lyon, Pelican, Boule d'Or, Album Fimbriatum, Val d'Andorre, Sarah Owen, M. J. Laing, Criterion, Elaine.

For twelve reflexed, not more than two of any variety, Mr. G. Carpenter was first with Amy Furze, Cloth of Gold, Cullingfordi, Golden Christine (2), Pink Christine (2). Mrs. Forsyth, Cullingfordi, Peach Christine, Putney George, Phidias. Second Mr. W. Mease, third Mr. A. C. Hookings. Twelve Anemone flowered, six good stands were exhibited, the prizes falling to Messrs. E. Coombs, M. Sullivan, and Mr. G. Carpenter. Twelve Japanese Anemones.—Mr. G. Woodgate was first in this class, Mr. Hookings second, and Mr. M. Sullivan third. Twelve Pompons, Anemones excluded, triplets.—The prizes in good competition fell to Messrs. W. Clark, Woods, and J. W. Read respectively. Twelve Anemone Pompons.—The prizes went to Messrs. Clark, Read, and Carpenter in the order of their names.

First-class certificates were awarded to Mr. E. Molyneux for magnificent blooms of Etoile de Lyon, and good examples of Miss Haggas. A similar honour was accorded for Lady Dorothy, a buff sport from Hero of Stoke Newington, exhibited by Mr. J. Buss, gardener to A. W. Aston, Esq., West Hill, Epsom.

Three miscellaneous groups were staged, Mr. J. W. Reed being distinctly first, Mr. T. A. Glover second, and Mr. J. Buss third.

Mr. H. W. Pitcher, gardener to Mrs. Dunnage, Surbiton, was the first in the Chrysanthemum group class, and Mr. T. Hunt, gardener to Cecil Boyle, Esq., Wimbledon, a close second. Mr. W. Skeet, gardener to J. F. W. Ponsford, Esq., Esher, and Mr. J. Sallows, Twickenham, won the chief prizes for large-flowered specimen plants, and Mr. Reed for Pompons.

Excellent exhibits of fruit, epergnes, bouquets, and amateurs' Chrysanthemums can only be mentioned approvingly as contributing much to the interest of the Show. The Exhibition was well managed by Mr. Woodgate (the Secretary), Mr. Puttock, and other officials.

FRUIT FORCING.

PEACHES AND NECTARINES.—*Earliest Houses.*—To have ripe fruit in April houses that are planted with Alexander and Waterloo Peaches may be closed now, fire heat not being applied until the beginning of December. Desirable, however, as are those varieties for forcing to afford very early dishes of ripe fruit, it must be borne in mind that they have not the quality of Hale's Early, Stirling Castle, or Royal George, which started at the same time will not afford fruit until May. The house must be kept close, but admitting air freely above 50°, employing fire heat only to prevent the temperature falling below 35°. The more slowly the trees are excited the stronger will be the blossoms. The outside border must be well protected with litter or dry fern, and if wooden shutters or tarpaulin are available they will be advantageous in throwing off excessive wet. A thorough soaking of water should be given to the inside borders, and if the trees are weakly a soaking of liquid manure not too strong will tend to a more vigorous break. Sprinkle the trees in the morning and afternoon of bright days, but do not keep them dripping with moisture, especially at night.

Succession Houses.—All the leaves are off, except in the latest house, where they should not be forcibly removed, at least not until they part readily from the trees, but when they are all off or come easily by brushing with the hand or a light broom, unfasten the trees from the trellis, prune them, cleanse them and the house thoroughly, and, if need be, paint the woodwork and trellis. Tie the trees to the trellis, leaving room for the branches to swell. Remove the surface soil and supply fresh, give a good watering to the inside borders, thereby having all in readiness for a start when required. The houses should be kept as cool as possible.

Lifting and Root-pruning Fresh Trees.—Any lifting, root-pruning, or the introduction of fresh trees should be performed at once, the planting being proceeded with as soon as the leaves are nearly off the trees to be removed. Trees for planting in houses are best if trained for three to five years to walls or under glass, and prepared for lifting by digging round them a year previously. Such trees can be lifted with an abundance of fibres, and being carefully planted they force well the first season, not being brought on too rapidly, and a moderate crop taken. It is always best to select these trees in preference to planting young ones, which do not fruit much the first two or three years, hence the advantage of planting trees in an already bearing state.

PINES.—Liberal ventilation should be afforded to houses or pits containing young plants whenever the weather is favourable, and avoid damping, as keeping the houses constantly saturated is more injurious than otherwise. Water will not be required frequently, yet the plants must be examined every ten days, watering such as require it, as too

great dryness is more injurious than otherwise, indeed extreme dryness is more prejudicial than is commonly supposed.

In the fruiting department lose no opportunity of closing the house at 85°, keeping the night temperature at 70°, or a few degrees less in cold weather. Remove all the superfluous suckers, retaining one only, the best on each plant. Suckers that appear on successional plants before the fruit is visible should be removed unless increase of stock is urgent. At this time of year it is usual to make new beds of fermenting material for the young plants. Tan is unquestionably the best, a good substitute being found in Oak or Beech leaves, which should now be collected as dry as possible. In forming beds of leaves they must be firmly pressed; tan, on the other hand, should be placed lightly together.

STRAWBERRIES IN POTS.—Possibly there is no greater error in growing Strawberries in pots than placing them in Peach houses and other structures with constantly open ventilators, where from the passing currents of air evaporation is constant and excessive, which only wastes the energies of the plants, and not unfrequently destroys the roots at the sides of the pots. All plants for early forcing should be in frames with a view to protect them from heavy rains only. Those for mid-season and late forcing are as well plunged in ashes in a sheltered situation as anywhere else, having a light covering of bracken or straw in severe weather. Drought is the great bane of the Strawberry, therefore those in frames must never be neglected, the soil always being kept moist.

Plants of Noble, La Grosse Sucréc, and Vicomtesse Héricart de Thury (we name them in the order we have found their merits for early forcing) or other early sorts must be held in readiness for placing in the early Peach house, to which fire heat will be applied early next month, or in the Strawberry house if one exist. If the plants are not so forward as desired it is advisable to make up a bed of leaves about 2 feet high, and place the plants in a frame upon it, packing the spaces between the pots with damp leaves. The bottom heat at the base of the pots need not exceed 65°, the top being kept cool, 50° not being exceeded, and when mild draw off the lights. This will tend to promote activity at the roots and to push the crowns. After three weeks to a month of this treatment the pots must be withdrawn or raised if the bed be still warm, so as to insure the plants bearing the temperature of the Peach house or Strawberry house without check, as would be the case were they taken from a warm bed direct to the shelves. Plants for placing in vineries to be started next month require similar treatment. In case of plants having well-developed crowns and abundant roots the slight bottom heat is not necessary.

Those having the convenience of a house for forcing Strawberries will find it a considerable advantage in very early forcing to start the plants in mild bottom heat, and if a pit be employed having artificial heat, so as to maintain the top heat at 50° in severe weather, keeping them in it until the trusses are pushed clear of the crowns before removing them to their fruiting quarters. Time will be gained, and as a rule very careful treatment is necessary to secure a satisfactory result with the first early forced plants. If worms have gained entrance to the pots dislodge them with lime water, rectifying any defects of drainage.

MELONS.—Except in the latest house these are nearly over. The latest plants have the fruits just beginning to net, and will be ripe some time in December. They need a moist genial condition of the atmosphere to insure their swelling, damping the house in the morning and again in the afternoon, putting on a "chink" of air in the early part of the forenoon to insure the dissipation of the moisture that may have accumulated or been condensed, and induce evaporation from the foliage. The night temperature should be maintained at 60° to 65°, and 70° to 75° by day artificially, advancing as much as can be had from sun heat after the sun passes the meridian. The plants may have liquid manure about twice a week. The fruit will ripen, and prove acceptable even at Christmas and the new year.

Plants that set their fruit early are ripening. They should have ventilation constantly, and a temperature of 70° to 75°, with as much more as can be accorded by day, husbanding the sun heat, but not closing the house, withholding water from the atmosphere and roots.

KITCHEN GARDEN.

FORCING ASPARAGUS.—With suitable heat Asparagus may be forced almost as freely and to yield as many heads in November and December as it will in January or February, but it is of the first importance that the roots be well developed, not under four years old, and in the best condition. Roots that have ceased to be profitable in the open ground need not be forced in the expectation that they will become better under this treatment, but where it has been decided to do away with any old plantations the roots may be forced, if only to obtain a few heads. Forcing need not be entered into so fully at this time as in spring, but all who can spare a few dozen roots should force them at present, or to be ready by Christmas at the latest. Lift roots that are large and well matured. Do not break any of the rootlets in doing so, but keep them entire. Three dozen good roots will give several hundreds of useful heads, and we prefer this to larger quantities at long intervals. If the number mentioned above are put in once a fortnight from now until March there will be a constant supply of Asparagus for the table throughout the winter. The roots may be forced in any ordinary hot-bed, but they produce the heads more quickly in a pit where there is a bottom heat of 80°, and a top temperature of 65° or 70° can be provided. Here the heads will be ready for cutting in from twelve days to fifteen

days after the roots are introduced, and they will bear for a fortnight. The roots may also be introduced to warm corners near boilers or flues, and propagating boxes and pits may be profitably filled with Asparagus. In all cases a layer of soil should be placed under the roots. Pack them closely together in a layer, and cover the crowns with light soil, water them afterwards, and provide the temperatures suggested. If the forcing bed is near the glass and in the full light the heads will be more robust and green than if far away from the glass. Asparagus roots are of no further use after being lifted and forced at this season, and those who have not sufficient to give a full supply in the open at the proper time will make a mistake by forcing too freely, but surplus roots may be employed with advantage.

SOWING PEAS IN AUTUMN.—This is an old-fashioned way of securing an early supply of Peas in spring that is not so much practised now as formerly. It is simple and sure, and merits general attention. We have many means of forwarding Peas sown in spring, but we sow some now, and it is decidedly advantageous to amateurs and others deficient of protectors in spring, as the Peas remain hardy throughout the winter, not requiring artificial protection at any time. Their position should be in a sheltered hut warm and sunny aspect, such as is afforded on a south or east border. The soil must be rich, and not heavy or retentive, as this may cause some of the seed to perish instead of germinating, and the young plants do not grow freely in a stiff wet cold soil in winter. If the seed is sown on the same day as the soil is dug it will germinate better than if placed in a soil that has not been disturbed for some time. Only the round-seeded earliest sorts should be sown now. The rows may follow each other if on a border, but if taken across a large quarter one or two long rows may be sufficient, and we generally find these do as well, particularly when podding in May, as those sown in rows 6 feet or 8 feet apart on a border. Open the drills to a depth of 4 inches, cover carefully, and tread the soil down over the seed. This will make the plants robust, and they will not suffer so much in severe weather as those growing in loose soil. But it is no use anyone sowing Peas in autumn unless they intend taking care of them. If mice are allowed to destroy part of the seed before it has been long underground, or slugs to devour the plants as soon as they come through the soil, it would be better not to attempt culture at this time; but if the same attention be given to them as is generally afforded young crops in spring these November-sown Peas will undoubtedly prove a great boon as a first and cheaply secured crop in 1890.

BROAD BEANS.—Broad Beans sown at this time also will pod before any sown in spring. They succeed in a heavy but not a wet soil. One pint of seed would furnish sufficient plants to produce several dishes of early Beans. Plant 4 inches below the surface, and see that the seed or plants are not injured by the pests that are injurious to the Peas. Young plants allowed to be partially eaten at this season fail to recover like those similarly checked in the spring and summer months.

CELERY RIDGES.—Large heads of Celery are apt to suffer considerably by the soil around them being excessively moist at this season. Heavy and frequent rains soon saturate it, and premature decay follows; but much damage may be prevented by going over the ridges and beating the sides smooth and firm with the back of a spade. This should always be done after frost or whenever the ridges have become loose and porous from any cause.

MUSHROOM BEDS.—Form more of these in sheds as fast as materials can be collected. They will yield a supply of Mushrooms at a time when vegetables are becoming scarce on the table and expensive in the market. This produce never exceeds the demand in winter. Gardeners and amateurs should therefore grow them largely, and many vacant sheds might be profitably filled with beds. The manner of forming these and their principal after treatment is now so well known as not to require detailing here, but for quick returns the beds should be spawned before the heat recedes from 88°, as unless the spawn becomes active at first it will never make satisfactory progress. Extremes of heat and cold, as well as extremes of wet and dryness, should not be allowed, as any of these conditions will injure the crop and check the supply. One of our large beds formed in a cool shed and spawned on October 1st is now bristling with "buttons."

LAND FOR CARROTS AND PARSNIPS NEXT YEAR.—It is well known that Carrots and Parsnips cannot be grown straight and clean in soil that has been manured immediately previous to sowing, as when they come in contact with the rough manure they twist and fork and become deformed. It is therefore desirable that all land for these crops that require manure should have it applied as soon as possible, and if dug or trenched well under the soil it will be decayed by February or March, and the soil will be in faultless condition for the production of the roots, especially if a quantity of soot and a little salt be added to the manure.

yield has been rather under than above the average; but even with that there will be a balance in favour of most bee-keepers.

I am in correspondence with many bee-keepers, and the general tone amongst them is in accordance with the foregoing. One bee-keeper and farmer from the east of Scotland writes, "I shall have less time now to attend to my bees, yet have no thought of giving them up, for they have been again this year not the least profitable item on the farm. I did not lose a single stock last spring, and I have taken on an average 40 lbs. from each stock; the best one yielded me 85 lbs. I put three swarms into one of the 'Lanarkshire' hives, and in less than a fortnight they had over 50 lbs. of super honey in addition to this. All my stocks are extra heavy, and will require no more attention till next summer."

The above has been copied, not because there is anything extra in the quantity of honey gathered, but because it has the ring of candour in it, showing only what has been taken, not what might have been, which would be at least as much again. The labour was reduced, and at the same time the probability of a full harvest next season without expense secured, in every way suitable for a busy man. Some bee-keepers take all the honey they can, and then feed the bees, which swells the profit to outsiders, but conceals the other side. The success of the above bee-keeper dates back some three years, when he became a convert to my system of bee management, as is the case with many others, and I trust that the number will increase.

FOUL BROOD.

Foul brood was ably written about in this Journal thirty years ago, and was fully mastered by "A Renfrewshire Bee-keeper" by the "Purgatorial process," much on the same lines, but a more radical process than what had been practised in Scotland for at least a century before. In all my experience I never knew a recurrence of the disease when bees and hive were properly treated, which cannot be said of other so-called cures.

In giving advice on the treatment of foul brood some writers have stultified their opinions on other things relating to the hive and the bee. For example, it was ludicrous to attempt to cure a colony of bees that was not in existence, because according to the writer's theory bees existed about forty days only, so that before the disease became virulent there would not be a living bee. Happily bees live much longer, and there should not be any half measures to eradicate the disease; but on its first appearance consign the contents of the hive to the melting pot, but not the bees. Disinfect the hive, then bake it and submit it to sulphur fumes, and after a few months repeat the process. In the meanwhile feed the bees; after two days' starving, and after combs are being built destroy them again, and repeat the process a second or third time, after which put the bees into their permanent hive, and if possible discover the cause of the malady.

The causes of foul brood are various, apart from contagion. It arises from some exciting cause or other, overheating being the worst, but damp brings about the same condition of things. It is many years since foul brood existed in my apiary, the first-named cause being the direct one prior to 1860. I had some trouble with it afterwards through infection from bought-in stocks, and have experienced much of it since in other apiaries, every case pointing to overheating or dampness. It is the latter I wish to caution bee-keepers against.

When the floor and the alighting board were in one piece, as is in many cases at the present day, the rain often entered, either from the alighting board or at the back, or some other part of the board that was improperly protected, until the whole of the floor was saturated, which cooled the interior of the hive so much that the perspiration from the bees was condensed inside, upon the combs and walls of the hive, and even so when of straw, while the damp condition of the floor was inimical to bee life, the result being that dysentery was prevalent, and few bees could reach the entrance, the greater part of them dying as they touched the floor, until the doorway became blocked, and the greater part, if not all,

THE BEE-KEEPER

NOTES ON BEES.

THE present year, generally speaking, cannot be said to have been a very productive one in honey, although in certain localities the yield has been abundant. Taking it all over, however, the

of the bees perished, a thing I never saw in my own apiary nor where the floor and hive were kept thoroughly dry. It is well known that I have for many years been advocating the narrow entrance and ventilating floor, an improvement on the eke belonging to the Stewarton, and have never had occasion to clean a floor.

The wide doorway, long since given up by me, is still recommended by some. The evils, which are sure to arise from it in certain seasons, are not unlike what are described above with damp floors. Dry combs, dry hives, and a dry atmosphere are the best conditions for wintering bees, and to secure these adopt the narrow doorway and ventilating floor. We have generally, particularly during winter, a damp atmosphere to contend with, when exposed things such as hives assume a greater or less degree of dampness, according to the nature of the material. Wax is a good non-conductor, but hives are deficient, and honey absorbs much moisture, and renders it injurious to the bees. A wide doorway is conducive to these evils, while it lowers the temperature of the hive, furthering the condensation of the perspired moisture from the bees upon the combs, walls, and floor of hive, thus bringing about the same condition of things as used to be the case in the more primitive hives, which the latter ones under proper management have an entire immunity from. It will be more to the advantage of bee-keepers to adopt the Scotch hive and advice than have need to be taking the advice of others to destroy bees suffering from a malady brought about by keeping them in improper hives and under similar treatment, which doubtless can be averted.

When the interior of a hive is made draughty by having a wide doorway the bees, to keep up the heat, consume more honey, perspire more, which from the coldness of the hive the bees are unable to expel, is consequently condensed inside, and the more protracted the cold is the more injurious it becomes to the bees, with a less degree of chance for their safety. Whatever is done, let it be of such a nature as will tend to keep the atmosphere and hives dry. Bees are always most healthy when they are kept in such a way that the slightest interference enables them to fly out. In this way less food is consumed, breeding goes on more briskly, and bees are strengthened, so that when they fly out they can return with safety and with little effort, while disease will be unknown.—

—LANARKSHIRE BEE-KEEPER.

* * All correspondence should be directed either to "THE EDITOR" or to "THE PUBLISHER." Letters addressed to Dr. Hogg or members of the staff often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post, and we do not undertake to return rejected communications.

TO CORRESPONDENTS.

In consequence of the extraordinary pressure that will be experienced during the *Chrysanthemum* season questions cannot be answered with the usual promptitude, and especially those arriving after Saturday. See notice below relative to the naming of fruit.

Books (W. B.).—You will find explanations of most of the terms named in the "Cottage Gardeners' Dictionary," post free from this office 8s.

Early Rhubarb (W. H. S.).—We have no "offer" to make on the

subject of your note. We do not approve of Rhubarb that pushes its growths through "thoroughly sodden manure out of the open yard," as such manure varies considerably, and as a rule impairs the quality of the produce.

Varieties of Cut Flowers (W. P.).—When the schedule reads, as it usually does or ought, "Eighteen distinct varieties of cut flowers," each bunch should consist of one variety only, as to introduce two colours is a manifest evasion of the conditions of schedule, as there is not one, but two varieties, and the stand should be disqualified as containing nineteen instead of eighteen as required.

Trellis for Peach Trees (D. H.).—Having trees on the back wall it is almost a necessity to have the front trellis low, so that the light may pass unobstructed to the trees on the back wall. There is no question, however, of the trees doing best trained to a trellis about a foot from the glass, and by utilising the whole of the roof in that way the fruit is not only much finer, but, taking all things into consideration, quite as much is obtained as when there are trees on the back wall, which in case of your having the trees trained to a trellis fixed to the roof is practically of no use for Peach trees. We have all ours trained to the roof, having trees only in front, and the back wall is used for Roses. The preparation of the border seems to be good.

Sulphide of Potassium as a Remedy for Mildew (S. F. B.).—All the sulphides and sulphur solutions have a discolouring effect on paint, which in some cases is highly objectionable, the discolouration on white paint being such as to preclude its use in structures where appearance is studied. It is, however, an excellent remedy, we using it at the rate of quarter of an ounce per gallon for slight attacks, and ordinarily at the rate of 1 oz. to a three-gallon watering pot of water. It is readily soluble in water, to which it imparts the appearance of milk. Plants, of course, can readily be syringed by laying them on their sides, or in such position as will prevent the soil being saturated, and turning round so as to wet the affected parts thoroughly with the solution.

Hydrochloric Acid for Killing Weeds on Walks (C. S.).—The solution of this acid in water is, as you are no doubt aware, the muriatic acid of commerce, the aqueous acid being also known as spirits of salt and marine acid. It is likely it would prove an effective weed destroyer, but we have no experience of it for this purpose, and it is probable has not been generally used for this purpose. Muriatic acid contains about 32·6 per cent. of pure hydrochloric acid. It is probable that this diluted with 99 parts water would be sufficient to destroy weeds on walks, and being applied in spring would keep them free during the season. That, however, is matter for experiment. We should be obliged by those having experience of this substance for the destruction of weeds furnishing particulars, or any other they have found efficacious and safe.

Chamærops Out of Doors (M.).—The well-known *Chamærops humilis* is the hardiest of Palms in cultivation, and is the only one found in Europe. This in the south of England succeeds well out of doors, and needs no protection; but in exposed cold or damp situations, even around London, it is frequently injured during winter if not protected. The same remarks apply to *C. Fortunei*, which is, however, generally less hardy than the other, though in some gardens it requires no protection. Two of the finest specimens we have seen are at Heckfield, Winchfield, Hants. These were planted in 1869, and now have massive trunks and large heads. The plants or trees have had no protection afforded them since the first winter after they were planted, but they are supported with fresh soil annually, the turf being removed for that purpose and laid down again. It is to this care that must be attributed the large, handsome, glossy leaves. They are well matched in every respect, as they are not only of the same size but of different genders, and are the parents of many plants that have been raised from them since they were established in their positions. No doubt they would succeed equally well in your district if the soil is not too heavy.

Perpetual or Spinach Beet (Amateur).—The following note was published, and it is to that you probably refer. "The Perpetual is not considered so good flavoured as the ordinary Spinach, but if a little extra attention is paid to the cooking it would go unnoticed at the table by many of the less keen judges. It appears strange that such an easily grown plant should be so little known amongst gardeners, as many have exclaimed when passing through the garden here, 'What is that you have there?' when the reply given was Spinach Beet. Here Spinach is most appreciated in early spring and in the autumn and winter. When other choice vegetables are plentiful in summer Spinach is overlooked; that is to our advantage, as the ordinary varieties behave very indifferently on our soil, and I have known the same to be the case in other gardens. It is common in many places to see this vegetable assuming wonderful size, requiring much thinning to do it justice, but it is not so with us. We have tried artificial manures, lime, salt, wood ashes, soot, horse and cow manures, but all to no purpose in obtaining a luxuriant crop of Spinach. In future it is our intention to sow the round variety for early spring crops, and the Perpetual for autumn and winter supplies. Our seed of the latter variety was sown from the second week in May to the middle of June, and we have been able to pick quantities of leaves for some time; in fact, we could have picked all the summer had the demand rendered it necessary, and we hope to continue it for a long time yet to come. When this variety is grown strongly the stems can be cooked and used like *Seakale*; but I have only known it used as such in one or two instances, yet I see no reason why it should not become an established rule."

Names of Plants.—We only undertake to name species of plants, not varieties that have originated from seed and termed florists' flowers. Flowering specimens are necessary of flowering plants, and Fern fronds should bear spores. Specimens should arrive in a fresh state in firm boxes. Slightly damp moss, soft green grass or leaves form the best packing, dry wool the worst. Not more than six specimens can be named at once, and the numbers should be visible without untying the ligatures, it being often difficult to separate them when the paper is damp. (*G. S. R.*).—1, Apparently a Euphorbia like *E. Cyparissias*; 2, Pyrethrum uliginosum, quite distinct from *Chrysanthemum leucanthemum*; 3, *Centranthus ruber*; 4, *Nephrolepis exaltata*; 5, We cannot recognise so small a scrap. (*W. C.*).—1, Insufficient without spores; 2, *Asplenium formosum*; 3, *Adiantum trapeziforme*; 4, *Gymnogramma chrysophylla*; 5, *Polypodium aureum*; 6, *Adiantum macrophyllum*.

Names of Fruits.—The names and addresses of senders of fruit to be named must in all cases be enclosed with the specimens, whether letters referring to the fruit are sent by post or not. The names are not necessarily required for publication, initials sufficing for that. Only six specimens can be named at once, and any beyond that number cannot be preserved. (*W. S.*).—1, Perhaps local; 2, Duke of Devonshire; 3, Waltham Abbey Seedling; 4, Golden Winter Pearmain. (*H. F.*).—1, Alfriston; 2, Out of character; 3, Cats-head; 4, Dutch Mignonne; 5, Annie Elizabeth; 6, Schoolmaster. (*A. M. M.*).—The Pear you send is probably Beurré Chairgeau. It was raised at Nantes, and distributed by M. de Jonghe of Brussels. We cannot possibly determine to whom some parcels of fruit belong. When several collections of six and of three fruits arrive, without the names of the senders in the boxes, letters by post do not remove the difficulty of identification. All the fruits are named, that can be named, which reached us before Monday of the present week.

*** In consequence of Dr. Hogg's absence from London fruit sent to this office cannot be named by him during the present month.*

THE FLOCK IN WINTER.

UNLESS draft ewes or crones are taken from the home farm flock or can be purchased by selection at so low a price as to render subsequent profit a certainty, we can hardly recommend them for winter folding, for there is the almost certainty of a heavy per-centage of loss, as well as the doubtfulness of any profit except that of fertility imparted to the soil. The frame of a crone may be of large size, but it requires a terrible lot of filling out before it is ready for the butcher, and then the flesh is never so heavy as that of a prime young hogget. This is doubtless the reason why some farmers will have nothing to do with crones, and press them upon the market when the lambs are weaned. We are bound to admit that they often do so both wisely and well, but we have repeatedly found it answer our purpose to purchase crones when good ones could be had.

An important point to be kept well in view at the home farm is a full supply of farm produce for family requirements. It is said that old mutton is a thing of the past, that the taste and liking for it is gone, that sheep are brought to such early maturity that upon many farms wethers see nothing of winter except as lambs, being fully developed and disposed of at seven months old. But let the home farmer who has to supply the table of a connoisseur make a special selection of draft ewes, bring them into high condition in winter folds, and so regulate his supply to the household that the mutton is always well matured in the slaughter house store before delivery, as much attention being given to the date of slaughter as to that of game, and then he will find that old mutton is cared for, and that his pains are well bestowed. So highly is it appreciated that we have known a leg of it to be sent as a present from one connoisseur to another as a tit bit not to be had from the family butcher. Depend upon it there is something more for the home farmer to aim at than just keeping up the regular household supply. It is possible for him to render that supply altogether so superior to the ordinary farm produce that the owner may proudly make presents to his friends of specimens of it as something rich, rare, and toothsome, a veritable *bonne bouche* fit for the table of a prince.

The early maturity of hoggets is both a matter of breeding and feeding. Hampshire Downs were first brought on sooner than other breeds by the use of lamb tups, then came high pressure feeding from the day the lambs began to eat, and that quick return from outlay, so desirable from a commercial point of view, was achieved. The commercial aspect of farm management is by no means to be ignored by the home farmer, and he is bound to give due attention to the profitable management of sheep for sale, and so to manipulate the young stock that each section of it may answer its legitimate purpose. The earlier hoggets have by this

date been sold at ages ranging from seven to nine months ; others that when weaned were turned out on pasture, and with the exception of stubble corn had nothing but green food till Turnip folding began, have now some dry food in troughs regularly, and heavy bills for eake are run up during winter upon many a farm, which tell seriously upon profits later on. We hold that sheep fatten equally well and far more economically upon eorn, which may or may not be home grown. It may answer best to sell a fine sample of corn, and purchase an inferior one for feeding purposes. Whatever may be used it is well to proceed with caution, and not rush into extremes by taking the hoggets at once from grass only to a full dietary of eorn or eake. Our aim is not only to finish the hoggets for market, but to finish the whole of the folding that is required to be done before the ewes and lambs are taken upon the land next spring. The entire matter is one of simple calculation, which may be worked out before making a single fold, and if this were done more generally it would tend to check much rash and unnecessary expenditure upon eake.

We know a great flock-master who at the present time has some £10,000 invested in hoggets, all of them being kept going quietly upon Turnips, with just enough dry food to keep them sound, healthy, and in store condition. They will be gradually dispersed in small or large lots, to be finished in folds by the buyers, into whose hands they will go quite ready for high feeding. The store hoggets are not confined steadily to the Turnips, but are given a daily turn for a few hours on pasture, to which they may occasionally be withdrawn altogether in very wet weather—not, be it understood, to low-lying wet pasture, but to that which is sound and well drained. It is not every farmer who has the much-valued upland pasture to turn to now, but there are few farms where really sound pasture cannot be had.

(To be continued.)

WORK ON THE HOME FARM.

Dairy cows are now being gradually settled in the yards for winter, and they will soon be withdrawn altogether from the pasture, and it will depend very much upon yard management whether the dairy produce continues good throughout winter. We saw recently a small barn that had been converted into a cowhouse, and it appeared to us quite a model building for the purpose. The cow stalls were along each side, with a wide passage down the centre of the building. The entire floor was of concrete faced with Portland cement, that of the stalls sloping gently down to a shallow gutter to carry off filth. The floor could thus be kept thoroughly clean, and pure air was insured by ventilators in the lofty roof, precisely similar to those of a Newmarket training stable. Each ventilator is a capped wooden shaft, with transverse openings at intervals in the part projecting above the roof, with a narrow sloping ledge over each opening to keep out snow and rain. Such ventilators insure pure air, and are altogether preferable to windows or shutters.

Next to a good cowhouse are the yard and open sheds. Yard drains have recently been put to a severe test, and any fault should at once be set right. We like cows to have some exercise daily, and a large sheltered yard—large enough for a stack of litter in the centre—answers best. Many such a stack have we had of bracken, sedges, rushes, and coarse grasses from bog land which cattle would not touch. Such litter requires no other care than to be carted to the heap when dry, and when it can be had straw can be saved for other purposes. The best enclosures for the cow yard are open sheds ; so that these are deep and commodious it is quite immaterial how roughly they are constructed. As we write we have in mind a very home-spun affair ; a lodge we once had built of unsawn timber with the exception of the plate, ridge, and eave boards. The ends and back had larch slabs with the bark on, and the roof with a high and steep pitch was thatched with Heather. On the yard side it was open, but it was so wide as to afford perfect shelter from rain, and there was a low, wide manger all along the back where the cows were fed on wet and stormy days. Get the cows settled now in some such yard for the winter, see that the water is pure, the litter dry, fresh, and clean : see also that the food is wholesome, that udders, hands, and pails are clean for the milking. Try also to have a cow calving at intervals of two or three weeks, and you will do very much to insure good butter during winter.

DYSON'S WOOD GRASS MANURING EXPERIMENTS.

MR. MARTIN J. SUTTON'S interesting series of experiments with different manures on grass have been previously referred to, and the following are some of the results of the experiments :—In experiment A on old pasture land, some of the plots that have been manured every other year have yielded less than the plot that has received no manure

whatever since the commencement of the trials in 1886. The latter yielded 27 cwt. 3 qrs. of hay ; but plot 2, which was manured in 1888 with 1 cwt. sulphate of ammonia, has yielded without dressing this year only 22 cwt. 3 qrs. of hay ; and still worse, plot 3, which had 1½ cwt. of nitrate of soda last year, has afforded in 1889 only 13 cwt. 3 qrs. of hay. This thoroughly supports Mr. Sutton's view that annual dressings do harm to grass lands unless repeated every year. The results are repeated similarly on experiment B, the seven years old pasture, where Cocksfoot has become so abundant, only the effect is not so strongly marked. Plots 7 to 18 in both experiments A and B have received manures of different kinds this year, with the exception of 11, which has remained unmanured. The greatest excess of produce over that of the latter has in experiment A been in plot 10, which received 3 cwt. of guano at a cost of 21s. 9d. per acre, the hay yielded being 36 cwt. 2½ qrs. The next highest yields were 31 cwt. 2½ qrs., on plot 12, manured with 4 cwt. basic einder and 2 cwt. kainit, the cost being only 10s. 6d. per acre, and 31 cwt. 1 qr. on plot 15, manured with 1 cwt. nitrate of soda and three-quarters of a cwt. muriate potash, the cost being 17s. 6d. per acre. The plots similarly manured in experiment B, on the seven years old pasture, made good returns also, the Peruvian guano one yielding 36 cwt. 1½ qr. of hay, the basic einder and kainit one 32 cwt. 1½ qr., and the nitrate and muriate of potash one 39 cwt. 3 qrs., and there was another heavy yielding plot in this section, that manured with 3 cwt. dissolved bones at a cost of 18s. per acre, the yield of hay being 38 cwt. 1½ qr.

Interesting as the above results are, those obtained from Mr. Sutton's new set of experiments commenced this year appeared to be still more valuable, founded as they were chiefly with the object of comparing fresh combinations of manures specially to prove whether kainit, nitrate of potash, superphosphate or basic einder, or what proportions of them mixed are best to be applied in conjunction with sulphate of ammonia and nitrate of soda. The subjoined table shows the yields of those plots which were heaviest, setting them in comparison with the crop of the plot that had nothing. The fact must not be forgotten, however, that one season may be more favourable to the action of certain manures than another season, and basic einder has done better in Mr. Sutton's grass plots in 1889 than it was found to do in previous years.

No. of Plot.	Manure applied per acre.	Cost per acre. s. d.	Weight of hay obtained per acre. tns.cts. qr.
1	Nothing	—	1 13 3½
5	Raw bone meal, 3 cwt.	18 0	1 14 1½
9	Farm dung, 10 tons	60 0	1 16 2½
12	Peruvian guano, 3 cwt.	34 10	2 0 1½
13	Basic einder 6 cwt., kainit 2 cwt.	16 0	2 1 0½
14	Superphosphate, 3 cwt., kainit, 2 cwt.	12 3	1 19 3½
15	Superphosphate, 3 cwt., nitrate of soda, 1 cwt.	19 3	1 19 3
16	Superphosphate 3 cwt., nitrate of soda 1 cwt., kainit 2 cwt.	23 3	2 2 1½
17	Superphosphate 3 cwt., nitrate of soda 1 cwt., muriate potash ¾ cwt.	25 7	2 0 0¾
23	Sulphate of ammonia 1 cwt., kainit 2 cwt.	16 6	1 16 1½
24	Sulphate of ammonia 1 cwt., kainit 2 cwt., superphosphate 3 cwt.	24 9	2 1 3½

All the manures were applied in the spring of 1889. The dung, bones, basic einder, kainit, and muriate of potash were applied to the plots on March 8th. The superphosphate of lime and guano were applied March 18th. The sulphate of ammonia on April 15th, and the nitrate of soda on the 22nd of April.

REMARKS.

3rd.—Wet all day ; dull damp evening.
4th.—Cloudy throughout.
5th.—Fog early, hazy morning ; bright afternoon, and fog again in the evening.
6th.—Generally cloudy, but some sun in the afternoon ; bright moonlight night.
7th.—Dull all day.
8th.—Bright and mild.
9th.—Slightly foggy early ; fair day, with some sunshine.
The fifth or sixth consecutive week of almost precise ly the average temperature.
Pressure high, and only one day with rain.—G. J. SYMONS.

PEARS—WHAT TO PLANT.

IN TENDING growers for market have had plenty of sound advice offered to them lately in the pages of the *Journal of Horticulture*, and although much of this ought to prove equally valuable to private cultivators I shall yet venture to offer a few remarks for the especial benefit of the latter. Amateurs in particular are often puzzled in the matter of ordering trees, both as regards suitable varieties and the best form of tree to plant. Now there are considerable numbers that are not worthy of occupying valuable wall space, and several varieties that are usually good in quality yet ripen at a time when Pears are most abundant. A haphazard selection may be the easiest way out of the difficulty, but it is the most unsatisfactory in the end. I hold Pears to be the most valuable of all hardy dessert fruit, and that they well repay for any trouble rightly directed which may be taken in their cultivation.

Of early varieties the best is undoubtedly the Jargonelle, and this is seldom satisfactory in the open, but requires unlimited wall space to have it in perfection. The heaviest crops and the finest fruits are obtained from trees occupying the sunny fronts and ends of dwelling houses and outbuildings, which the trees rapidly cover. The next best positions for it are rather high garden walls with a south or south-east aspect. It is a rank grower, hence the need of good space. Williams' Bon Chrétien trained against a wall of almost any aspect seldom fails to produce heavy crops of fine fruits; but as these keep badly, and seeing that standard and pyramid trees are quite as productive, the fruit also being equally satisfactory, only those with plenty of wall space ought to devote any portion of it to the "Williams." Souvenir du Congrès resembles the last-named, and may be grown in many fruit-growing districts to a much greater size. It keeps rather longer, succeeds under any form of training, and may well be grown where large collections are preferred.

Beurré d'Amanlis usually closely succeeds Williams' Bon Chrétien, and is a very serviceable variety; it forms a good pyramid, is a sure bearer, and produces still finer fruits on wall-trained trees. British Queen with us is not a strong grower, but against a sunny wall it rarely fails to bear. The fruit are of medium size, ripening during the early part of October, and they are very buttery and sweet. Beurré Superfin forms a handsome standard, and is very prolific and good in point of quality. Wall-trained trees produce much the finest and most clear-skinned fruit, and on the whole it may be said to merit a place in every collection, however limited. It is an October Pear, and keeps fairly well after ripening. Fondante d'Automne unfortunately ripens at a period when several other good varieties are in season, but it is yet worthy of general cultivation either against a sunny wall or in the open. With us it ripens late in October, and does not keep long.

Pitmaston Duchess has rapidly become very popular, especially among exhibitors and lovers of showy fruit. It succeeds admirably as a pyramid, and crops very heavily. Wall-trained trees, however, are best calculated to produce show fruits, which they rarely fail to do. It is in season during October, and may be kept till the middle of November. There are many varieties I prefer to eat, one of these being Beurré Hardy, which ripens a few days later. This excellent Pear does well either as a pyramid or bush, and merits a place against a west wall. With Louise Bonne of Jersey everybody is acquainted; it forms neat and serviceable pyramids, and

the trees against walls of all but quite north aspects are very prolific and produce very clean handsome fruits. It is an October Pear sometimes keeping good till the middle of November, while the quality is fairly good, though the peculiar musky flavour does not suit all palates.

Marie Louise is even more generally grown than the last named, and may be classed as the most popular Pear in cultivation. Fairly good pyramids and profitable standard trees are frequently to be met with, but the best fruits are taken from wall trees. Any but the coldest aspect suits it, and the very luscious fruit may, if a little judgment is exercised both in planting the trees and ripening the produce, be had daily throughout October and up to the third week in November. Marie Louise d'Ucc'e is quite distinct from the last named, and not equal to it as far as quality is concerned. It, however, forms capital pyramids, and is one of the surest bearers.

Doyenné du Comice, in season at much about the same time as Marie Louise, is even preferred to the latter by many good judges of fruit. Altogether it is a grand Pear, and appears to thrive and bear well in any position, on any stock, and however trained. It should be included in the smallest selections. There are so many varieties, several of which I have named, available during October and the early part of November that it would seem superfluous to add more; yet I must not omit Maréchal de Cour. This is really an excellent variety, being suitable for either pyramids or wall training, is a good cropper, and the fruit is large, juicy, and sweet.

After the supplies of the foregoing varieties are exhausted there is a falling off, there being but few really good midseason and late Pears. Huyshe's Prince Consort succeeds well against sunny walls, and forms a good pyramid or bush. It is a good bearer, and the fruits are available about the middle of November. With us it is rather firm and dry, but as a rule the quality is fairly good. Beurré Diel we cannot dispense with. The quality, though better than usual this year, is never first-rate, but we have no surer bearer against walls of different aspects, while the fruits are of attractive appearance and available during the whole of November, and sometimes a fortnight later. Beurré Bachelier has long been a favourite of mine, and in my opinion ought to be more extensively grown. Good pyramids of it are sometimes to be met with, but such fine varieties merit wall space. The trees bear well, produce large fruits, which are of excellent quality, late in November, and keep well after they are ripe. Winter Nelis is one of the smallest varieties in cultivation, but there are few or none to surpass it as far as quality is concerned. It forms a neat pyramid, but very rarely is the fruit from such trees of any value. The finest fruit is obtained from double-grafted trees trained against sunny but not necessarily south walls. There are few better croppers, and the fruit ripens late in November, frequently keeping good till the end of December. Glou Morceau, another well-known variety, is very rarely presentable from pyramid or bush trees, nor can it always be grown to perfection against walls. With us it never fails, and many of the fruits are fairly large, clear-skinned, and luscious, the season usually extending from the end of November till January. Beurré d'Arenberg succeeds remarkably well as a pyramid or standard, and wall trees crop equally heavily and surely. The fruits, unless freely thinned, are rather small, and at their best are of fairly good quality during December and the early part of January.

Josephine de Malines must be included in limited lists, being one of the most valuable late varieties. It is only fit for training against walls of different aspects, and rarely fails to produce moderately heavy crops of medium sized fruits which, as a rule, ripen during January and keep good till the end of February. It promises to be very late this season, and may require a little heat to assist in the ripening. Easter Beurré varies surprisingly. It is generally very prolific, but in many instances the quality is second rate. Young wall trees produce much the best fruit, and with us pyramids are a failure; nor does it keep much after January

Bergamotte d'Esperen succeeds well as a pyramid or bush, there being no heavier cropper in cultivation. The fruits are rather small, and of fairly good quality as late as March. Much the same remarks apply to Olivier de Serres, this variety keeping even later. Jean de Witte is also small, but it is sure cropper either grown as pyramids or wall-trained trees. We have a large specimen against a wall facing north-east, and this rarely fails; it keeps till April and is fairly good in quality.

Beurré Clairgeau, though much grown, is fit only for stewing, and the same may be said of Duchesse d'Angoulême and General Todleben. Gansel's Bergamot is gritty; Doyenné Boussoch very large and handsome, but mealy unless eaten quickly; Van Mons Léon Leclerc, though handsome and good in quality, ripens when there are plenty of other better varieties available; but room ought to be found for Napoléon in large gardens. Beurré Bosc is sometimes good in quality, but as a rule is much too gritty, and Thompson's keeps but a short time. Hacon's Incomparable is a fairly good November Pear, and sometimes keeps well into December. Knight's Monarch, where it ripens well, is very delicious, and is especially good at the present time, but who can account for or prevent the premature dropping of the bulk of the crop? Beurré Sterckmans is unreliable, but is good this year. Nec Plus Meuris generally bears well, though in most instances is nearly all core. The best stewing Pears are Black Worcester Catillac, Spanish Warden, and Uvedale's St. Germain. Remarks on the selection of trees must be deferred.—FRUIT GROWER.

SILENE SCHAFTA.

THE *Silenes* or Catchflies are among the most ornamental of our rock plants, and the above-named species, while it cannot be called either a new or rare plant, has a great claim for consideration in respect of its late period of flowering. The most enthusiastic of the lovers of Alpine plants cannot deny that the rock garden in autumn is comparatively deficient in bloom, and from July to September this little *Silene* opens its flowers to our admiring eyes, showing us that with its aid the rockery need not be devoid of brightness.

The late-flowering Catchfly was first brought before the public by Dr. Hohenacker, who published an account of it in the "Proceedings of the Imperial Natural History Society of Moscow" for 1838 under the name of "*Silene Schafta* of S. G. Gmelin," and stated that "it grows naturally in rocky places, on a mountain called Keridach, in the district of Suwant, in the Russian Province of Talsch, at the height of from 2500 to 4000 feet, flowering in October."

S. Schafta was sent to the Horticultural Society of London in 1844 by Dr. Fischer, who obtained it from the Botanic Garden at Dorpat, and was described in the Journal of the Society as a "beautiful little herbaceous plant, producing a great number of spreading slender downy stems, which form compact tufts, and are terminated near the extremity by four or five bright purple flowers more than an inch long." "Of these flowers that at the extremity of the shoot opens first, and those below it one after the other in succession, so that the branches are by degrees quite covered with blossoms. Its stems do not rise above 6 inches high." It is rather curious to observe the various statements as to its colour. Mr. Wooster says it is not purple, but pink; another author, in "*Alpine Flowers*," calls it purplish rose; and Glenny's "*Handbook to the Flower Garden*" calls it deep rose. For my own part I am disposed to agree with Wooster, although it is certainly darker in colour than it is figured in that author's "*Alpine Plants*," to which work I am indebted for the history of the plant. It is impossible to be dogmatic on the question of the precise shades of flowers, and no one need envy the one first called upon to describe the colour of a new flower.

S. Schafta differs greatly in appearance from the hard compressed-like tufts of the other Alpine *Silenes*, having a more trailing habit, which renders it admirably suited for hanging over rockwork or for a raised edging. Its strictly herbaceous habit prevents it being of much value where dwarf evergreen plants are required, but from its first showing its leaves until the termination of its flowering period it forms a neat and attractive object. The flowers are about half an inch across, and are produced so freely that little foliage is seen. It is perfectly hardy in the south of Scotland, and probably so throughout Great Britain, and is of easy

cultivation in light rich soil. The plant may be propagated by division, but the best method is by means of seeds, which are cheap and easily obtained.—S. ARNOTT.

NOTES ON OUTDOOR TOMATOES.

THE past summer has been a very good one for Tomatoes grown out of doors. With us the plants made strong growth free from disease, and the yield of fruit from nearly all varieties was extremely good. Tomatoes have become very popular in the last few years, so popular in fact that the supply is not equal to the demand, nor is it likely they will ever cause a glut in the market, as unlike Apples, Plums, and most other fruits, they do not ripen all their fruit at one time, but continue to ripen a few every week over a lengthened period. There is no reason why everybody with a small amount of glass and a moderately sheltered position out of doors should not successfully grow good Tomatoes, provided the plants are properly prepared previous to placing out. Our summers are so short that the best results can only be obtained when strong plants that will begin setting fruit as soon as placed out are used, and these should be ready by the last week in May or the first week in June. Many failures in outdoor Tomato culture can be traced to this cause alone—viz., planting thin lanky objects that have been too crowded whilst under glass. More fruit will be obtained from six sturdy short jointed plants than from two dozen weakly ones that have been drawn up in strong heat and much crowded.

For our main outdoor crop we sow seed thinly in 6-inch pots early in March, and place them on a shelf near the glass in a temperature of 60°. When the seedlings have made a few rough leaves they are placed into large thumb pots and returned to the same house. They are kept close for a few days to give them a start, after which abundance of air is given, to ensure slow yet sturdy growth. When the pots are full of roots the plants are placed either singly into 6-inch pots, or two are placed in 8-inch pots, always pressing the soil in firmly, for that induces a short-jointed growth and a disposition to fruit. As long as the plants are in the house they are kept well up to the glass, and abundance of air admitted on all favourable occasions. The first week in May we stand them out of doors in front of a south wall and cover them at night with tiffany, and in very cold weather the tiffany remains on all day. They grow very little the first week or ten days, but then it induces them to show fruit, an object which should always be secured before planting outdoor Tomatoes.

Our best crops were obtained from some planted in front of a Melon house with a south aspect. On the hard path and 14 inches from the wall we fixed planks 1 foot wide edgewise, which served to keep in the soil from the other part of the path. We placed in 4 inches of rough ballast for drainage, and on this 6 inches of compost, consisting of equal part of rather heavy loam, Mushroom manure, a fine ballast with a good sprinkling of bone dust. The plants were placed 1 foot apart on the 1st of May, and protected with tiffany on cold nights for a fortnight. Each plant was secured to a stake 9 feet high, at which height the growths were stopped; and this had the desired effect of concentrating the whole strength of the plants on the fruits and ripening nearly the whole of them before the frost set in. Of course the plants were grown on the single stem system, and all side shoots removed whilst very small, for I am convinced there must be neither loss of time nor material to ripen good crops of Tomatoes out of doors in the midlands.

Other plants from the same as above were placed out the last week in May under a south wall between fruit trees, and they carried very heavy crops but did not ripen so well as those planted on the path. This we attribute to the fact that they had unlimited room in a cold heavy soil. Outdoor Tomatoes should have very little soil to grow in, and the roots if possible should be under control.

We grew several varieties, all of which were good and remunerative, but we accord the premier position to a variety obtained from Messrs. J. Veitch & Sons, named Ham Green Favourite. It would be difficult to conceive a more perfect Tomato for outdoor culture. With us it set freely and swelled enormous crops of beautiful bright red smooth fruits, weighing from 8 ozs. to 12 ozs. each. It is very solid and heavy weighing, and has all the characteristics of a first class market fruit. Mr. Crocker, who is said to be the fortunate raiser of this splendid variety, is to be congratulated upon giving to the public a Tomato, the all-round qualities of which will only be surpassed with difficulty.

Carters' Traveller finished off a good crop of fruit. It is a very smooth medium size variety with a thin tough skin, and so far as appearance goes is a model.

Hackwood Park carried an enormous crop, but the fruits were very distorted and ugly, on which account we shall not grow it out.

of doors again. It sets freely through the winter, and under glass the fruits are a better shape.

Hathaway's Excelsior is a good variety for outdoor cultivation. In shape and colour it resembles Ham Green, but it did not grow so strongly nor carry so heavy a crop as that variety.

Holborn Ruby is a model Tomato for eating uncooked, it being the best flavoured variety I have ever tasted; it is, however, too small for market purposes.

Trophy gave us a few very large handsome fruits, but it is a shy cropper out of doors.

With Tomatoes there is no necessity for growing a host of varieties to maintain a continuous supply, hence what gardeners want is to find out the best all-round variety, and then grow it to the exclusion of all others. In this matter gardeners can help each other greatly by sending to the Journal the results of their trials and experiments with new varieties, provided they are based on well arranged methods.—J. H. W.

ORCHID NOTES.

DISA GRANDIFLORA.

No attempt should be made to hurry these plants or failure will certainly result. They appear to grow slowly (this is natural), and those who may be growing the plant for the first time may be tempted to push them on more rapidly. We have been in this position, and advise others to give them liberal supplies of water, a circulation of air daily, and a night temperature of 45°. Nothing is gained by giving the plants a higher temperature, but the reverse; it may force the growth up weakly for a time, when the foliage will turn yellow and the plants often dwindle away. In too close an atmosphere the plants frequently become a prey to aphides. These under any circumstances soon ruin the plants, and should be destroyed by sponging the leaves with a weak solution of tobacco water. The worst enemy we have to contend against at this season of the year are small slugs. They soon do much damage, and should be sought for attentively every evening. This appears to be the only means of eradicating them. We have removed the living sphagnum from the surface of our plants, and for some time lately have sprinkled soot over the surface of the pans every evening just before dusk. This certainly dislodges them; they come out in quantity a few minutes after the soot has been applied. Care is needed that the soot is not placed upon the foliage; no harm results from dropping it on the surface of the soil.

MASDEVALLIAS.

If *M. tovarensis* has not been shifted from the *Odontoglossum* house in which it has been grown during the summer no time should be lost in removing it to warmer quarters. It must have a temperature of 55° to 60°, in which it will pass the winter safely. Our plants stand very well in a warm corner of the *Odontoglossum* house, but in this position the temperature never falls below 55°. *Masdevallias* will require considerably less water than has been given them up to the present time. Mischief is often done by supplying them too liberally with water during the winter months and having too low a temperature. These are the evils that cause the foliage to be spotted. The soil about their roots should not be destitute of moisture, and the temperature must not be allowed to fall, even during severe weather, below 45°. Watch for slugs; they are particularly fond of the tender flower spikes as they appear. If aphides exist in the house they are certain to establish themselves on the young spikes; they must be cleared off at once by the aid of a soft sponge and clear tepid water.

DENDROBIUM HETEROCARPUM.

No advantage is gained as far as we have been able to discover by removing this Orchid to a cool structure. It will bear this treatment without injury, but it neither adds to the flowering properties of the plant nor increases the strength of its growth the following season. Cool treatment is given only when we are anxious to retard for any length of time a number of plants. This Orchid is generally rested with us at the coolest end of the *Cattleya* house. It will bear being kept very dry without displaying the least signs of shrivelling.

CŒLOGYNE CRISTATA.

Plants that were well ripened early by exposure to light and a good circulation of air during their last stages of growth, and then placed in a cool house, have their flower spikes nearly 2 inches long. A few of these we are introducing into a temperature of 60°; in fact, they are taking the place of the late plants that are ready for removal to cooler quarters. Less water will be needed while in this position, but on no account should they suffer from an insufficient supply. The temperature of the *Odontoglossum* house will be ample to induce them to rest. If they are kept too dry their pseudo-bulbs shrivel, which is detrimental to the production of large flowers and pseudo-bulbs another year. The atmosphere in which they are placed while given cool treatment should not be too moist. The driest position of the *Odontoglossum* house should be selected. In too much moisture during the period of inactivity the tips of the leaves are liable to turn black. This Orchid does splendidly suspended from the roof of a warm house while making its growth. It appears, however, to do better in pans than on blocks or in baskets. For all that require more root room another year suitable pans are being prepared with three small holes just below the rim, through which the wires for suspending them will be secured. Ordinary pans, hard burnt, are such as will be used with no holes in them except at the bottom and the three already named. Pans with a quantity of holes round the sides have an objectionable appearance when they turn green. For suspending purposes we shall use no more soft, or what are termed porous pots. Pot washing takes up considerable time, and the use of porous pots and pans for these plants is only a fad; they do equally as well in hard burnt ones, and the labour of keeping them clean is much less. Hard pots are a long time before they display signs of turning green. We have had some keep perfectly clean the whole season.—ORCHID GROWER.

ORCHIDS AT FOREST HILL.

THE following Orchids are now flowering in Messrs. John Laing and Sons' Forest Hill Nurseries:—*Cattleya exoniensis* (true) and *Bowringiana*; *Cypripediums* *Harrisianum*, *Haynaldianum*, *insigne*, *insigne albo-marginata*, *insigne sylhetense*, and *Sedeni*; *Dendrobium Jamesianum*; *Masdevallias* *candida* and *Veitchi*; *Oncidium* *Forbesi*, *ornithorhynchum*, *tigrinum*, and *Wentworthianum*; *Odontoglossums* *Alexandriæ*, *constrictum*, *fragrans*, *grande*, *Oerstedii* *majus*, the distinct *Insleayi*, and its beautiful variety *splendens*, which is much superior to the ordinary type and is very rarely seen.

VINE-PRUNING AND WINTER-DRESSING.

It is not to teach the learned, but the several inquiring amateurs who are now essaying the winter treatment of their Vines, and are not too confident of the procedure best adapted for their purpose, that a few grains of instruction are hereby scattered. Vine-pruning must be adapted to the age, condition, and peculiar state of the Vines. On these circumstances the system of winter pruning must be founded. There are two chief forms of pruning the Vine—the short spur and long rod. There are also modifications of these; or the two plans may often be seen in combination.

Let us start with a young Vine planted in the spring with a new rod to the top of the house. "Is that rod to be cut down?" "Considering the permanent welfare of the Vine, undoubtedly." "But will not that rod bear fruit if left alone?" "Certainly, if a stout perfected rod; moreover, the best bunches will not be near the bottom, but nearer the top of the house." "Then why cut it down? If it kills itself with work it may." That is the mode of reasoning of a self-knowing man, fond of asking advice and never following it. Picking up advice here and there, and going somewhat different from all, he gets a first show of Grapes, and glories in the result as being a "plan of my own," having particular care to emphasise the "my." The Vine stands. It carries some good bunches of Grapes, but many of the lower buds break stubbornly, some not at all, and the side growths, although pinched, are weak. Well, they ought not to have been pinched. Never mind, a lot of fruit is had, but the Vine is ruined. That is killing the goose which would have laid the golden eggs. Another stance: If, instead of pinching all the side shoots, at the base one is selected, the eye just at the bend where the cane turns down to the rafter generally breaks freely, and this allowed to grow to the top of the house unchecked, will make a good rod at the same time the other carries the Grapes. Now, if the rod-bearing cane is cut clean out when the Grapes are all cut, the young rod will be ready to bear more. That plan carried out year by year is the long-rod system pure and simple. But some may say, "Oh! everybody knows that." I beg pardon, everybody does not know, and it is just these who require the information, and to whom alone it is offered. To

assume that everybody knows everything, and that descending to simplicities is derogatory to one's reputation, is the great error of the times. If everybody knows a thing, why pen a line? and if we find one who looks with contempt on a thing plainly put, depend upon it that man is a hunter after information if he has need of it. But to proceed. That plan will produce a quantity of Grapes, especially if not followed out as stated, but if the first year's growth had been boldly cut down to the base of the rafter, and a year's grace given to get root-power, that seeming year's loss is really an eventual and permanent gain.

Those who want a large quantity of Grapes in a small space of time, and who have no reserve—nursing canes—will find this long-rod system give them; moreover, it is more than possible they will be less troubled with shanking and other ailments than by the spur system. Mind, that is for amateurs who do not understand the whole *rationale* of Vine-culture sufficiently to work without aid, and who desire a quantity of Grapes as easily as possible, regardless of the way it is produced or the appearance of the Vines producing it. By that plan the bulk of the fruit will always be at the top of the house. To obviate this, take up two reserve rods by the side of the fruiting cane. Stop one nearly halfway up, and let the other go the full length. That will fill a house with fruit from the bottom to the top of the rafters. The half-length rod may extend to the top in the year of fruiting, and it will make a fine bearer the following year. Another from the bottom, stopped halfway up, will make sure for the lower part of the house, and so the roof may be covered with fruit year by year, every bunch from wood of the year preceding, no spurs having had time to form. With a good root-power to begin with, this plan is capable of producing an immense quantity of Grapes. It is the simplest of all forms of Vine-pruning. Anyone can do it who can cut away a dead Raspberry cane after fruiting, and train one young shoot halfway up the stake for bottom fruit, and another the full length for top fruit for the next year's work. The bottom half of the rod reaching to the top should, however, be divested of eyes, and the eyes on the bearing portion be thinned out to about 15 (not less) inches apart. This can be done in the spring by disbudding, and is essential in preventing an overcrowding of foliage, the most common of all mistakes in Vine culture by inexperienced persons.

Leaving for the moment the long-rod or Raspberry system, let us look at the spur plan of treatment. The young rod of the first year should, if at all weakly, be cut boldly down to the bottom of the rafter, and not be allowed to bear a bunch. Strength will thus be concentrated to produce one fine young rod which, its other treatment being right, is sure to follow, and will lay the foundation for a good constitutioned Vine for permanent work. If, however, the cane is stout, strong, and well ripened, containing not more than a speck of pith, but is hard, round, and bright, then it may be allowed 2 to 3 feet of rafter, and to carry two to four bunches. It will perfect these, and make a fine extension cane at the same time without any danger of overcropping; indeed the fine cane is the proof—the safety-valve that all is right on that side, the bunches being, as it were, the steam-governors. If these press heavily, if the rod does not progress freely, relieve pressure by removing a bunch or bunches as required, making above all things sure that the sap has a full and abundant flow upwards to form a fine extension growth of vigorous cane. After this, yearly extension may at each winter's pruning be shortened to about a one-fourth length of rafter—that is, if the rafter is 16 feet, leave 4 feet. In very strong canes more is quite permissible, but as a rule that is a safe approximative guide. Now these side shoots which have borne the bunches must be shortened. This shortening forms the spurs. Cut very smooth and clean almost close to the main stem—that is, leaving only the lowest prominent eye that has had the assistance of a leaf. There can be no mistake there—the lowest eye that has had a leaf at its base to be left, the rest cut away. If the Vine is in a good state that eye is sure to push and show fruit. If this close shaving should frighten, two clear eyes may be left; this will give two shoots, and both will or ought to show bunches. In this case always rub one off, and let it be, if possible, the one farthest from the main stem. Some people will prune a Vine for twenty years, and in that time not produce a spur of 3 inches, while others will add to the spur at the least an inch a year. Close pruning is the best for this reason, that the lateral flow of sap is less impeded. Why? Look at an old standard Rose and its knotty swellings by yearly cutting. Note the narrow, restricted, twisted, curling sinuosities of the sap vessels. It bears small blooms, and well it may. Cut its head off, and see the immediate gross vigour of the after-growth. The impediment to free sap movement is removed; the narrow tortuous channels are substituted by free, open, sap courses. So it is with the Vine or any other plant. The plant—the Rose, the Vine—may not be in a bad state of health; the roots may be sound, and the foliage not indicative of any disease; the soil may not be

seriously at fault, but may be reasonably well supplied as the food store; yet, if not breaking down by disease, the plant may come far short of the perfectness of constitution desired, and fail in the character of bloom or fruit. The fault there lies in the transit of sap of food. In the Indian famine, Rice was plentiful while the natives starved, but a free channel of communication being provided the plague was stayed. I am not sure that I have seen this idea expressed before, but many an example of a stubborn scraggy tree tells me there is something in it. On that account close spur pruning is preferred to a longer mode, which in half a dozen years results in a curled knuckled accretion of wood and tissue through which the sap can only circulate by a sluggish crawl, inadequate to the real requirements of the fruit and foliage of the Vine it is attempting to feed. But an example may be in mind that Vines with long twisted spurs bear good and satisfactory fruit. Very well. Go on with the mode that answers. Nothing succeeds like success, and never change a plan that is satisfactory by whomsoever the change may be proposed.

Before closing these notes I should like to remark in the matter of a young Vine, that I do not think the common practice a wise one of divesting a young cane of all its eyes from the ground up to the rafter—that is, not sweeping them off at a stroke the first year. The upright sashes of houses may be from 4 to 6 feet. That portion of the cane is not often required to bear fruit; still, for a year or two it is preferable to pinch a few shoots, and have a little foliage there rather than leaving the stem absolutely bare. The rod of a Vine so trimmed never thickens in the same proportion as the upper portion of the stem. The sap channels are contracted, and often a rod will form a protuberance of incipient roots at the base of the rafter where foliage commences to get the nourishment it needs, and which the contracted vertical portion of the stem cannot supply. A little foliage down to the very ground will change all this. The stem thickens freely, and affords a sufficient medium of conduct for the free unimpeded sap-flow. A young Vine so managed will be as thick at the base, even thicker, than at any other part of the rod; but divest it of eyes the first year, 5 or 6 feet up from the bottom, and nothing can prevent it becoming thickest at the top, like a ladder reared wrong end upwards. In that case all the best fruit will be at the top of the house; in the other it will be equally good to the very bottom. This is not theory but practice.—J.

DORYOPTERIS PALMATA.

SMALL plants of this Fern, in neat little pots, are very ornamental and useful for decorative purposes, owing to the distinct appearance of the foliage. The examples shown by Messrs. J. Veitch & Sons, in their collection of table plants, were very notable, and it might well be introduced where variety of leaf character is admired. The fronds differ greatly in size; in young plants they are only a few inches across, but in older and stronger specimens they attain a height of 10 or 12 inches. They are of a bright glossy green colour, deeply divided in palmate fashion. The Fern is an evergreen from tropical America, and requires the temperature of a stove or a warm greenhouse, with a compost of peat and sphagnum and good drainage.

PLUMS.

[A paper read by Mr. T. Francis Rivers at the Horticultural Club, Tuesday, November 12th, 1889.]

THE Plum is, I think, destined to be one of the most important of our economic fruits, if we can establish the fact that fruit growing will be a profitable source of income in these islands; there is, however, little doubt that a fair profit is derived and will be derived from the employment of land for this purpose, although orchards can never take the place that seems to be claimed for them, by those who have never practically undergone the expenditure of capital necessary to succeed in this as in other occupations, which depend upon the millions rather than upon private consumers for the disposal of produce. Theoretically an orchard containing some 500 trees planted, as I think they may be planted, 9 feet row from row, and 9 feet in the rows, will produce, after a certain period of years, from one-half to one bushel per tree, worth 6s. to 10s. per bushel, according to the season in which it is sent to market, the early and late Plums realising a higher price than the midseason fruit. Theoretically also one grain of Wheat will produce three or four ears, each ear containing some thirty or forty grains. Altogether the gross produce, therefore, of a grain of Wheat seems to promise an enormous return, but the returns of the cultivators of land do not, however, show the enormous profit which in theory they ought to receive, and I may say that the practical cultivation of

fruit will disappoint the theorists who are unhappy enough to embark a large capital under the idea that certain crops will be realised. It is, however, very certain that with a suitable soil the cultivation of the Plum will give a handsome return, but the first condition of success must be in the choice of soil. It is perfectly well known to all practical cultivators that a calcareous soil is absolutely necessary, and although lime can be supplied by artificial means the non-calcareous soil cannot compete ultimately with that in which lime is a natural ingredient. This is recognised by Andrew Downing in his exhaustive book, the "Fruit and Fruit Trees of America." In a paragraph treating of soil he says, "The Plum will grow vigorously in almost every part of this country, but it only bears its finest and most

niceties of cultivation, and it is generally supposed that a Plum tree will grow anywhere, and, as a matter of fact, when planted for the supply of an ordinary household, both for the kitchen and dessert, the choice of sorts is an important matter, the Plum being so generous when well preserved that it will provide the table with a wholesome and delicious fruit all the year round. I will for convenience divide the use of the fruit into two sections—the dessert and the still room. Taking the dessert first, the earliest of these which ripens when the Bigarreau Cherries have become a source of regret, as things to look back to, is the Jaune Hâtive, or White Primordian, a pretty little yellow Plum, which surprises from its precocity, but is not valuable for any other quality, and has now almost fallen out of cultivation.

FIG. 55.—DORYOPTERIS PALMATA.

abundant crops in heavy loams or in soils in which there is a considerable mixture of clay. In sandy soils the tree blossoms and sets plentiful crops, but they are rarely perfected. It is also undoubtedly true that a heavy soil is naturally the most favourable one. In certain parts of the valley of the Hudson, near Albany, where the soil is quite clayey, the Plum is healthy, productive, and delicious, while in adjacent districts of rich sandy land it is a very uncertain bearer, a convincing proof of the great importance of clayey soil for this fruit." For clayey soils I think we may read calcareous. He also says, "We have found common salt one of the best fertilisers for the Plum tree, as it greatly promotes its health and luxuriance." I confess that I have never had the courage to apply common salt to my trees, considering the disastrous effects of salt generally upon fruit trees.

People are, however, more interested in sorts of Plums than in the

Rivalling this sort in precocity, and infinitely superior in flavour, we have the Early Favourite. This is a delicious Plum, which in warm seasons will ripen on a pyramid at the end of July, and on a wall during the middle of the month. The Early Green Gage is a very pleasant addition to the Plums of this month. It is not quite equal in flavour to the recognised Green Gage, but it is exceedingly good. I have lately been able to make an addition to July dessert Plums by the Stint. This is very rich and good, and is so dwarf in its habit that it takes no more room than a good sized Gooseberry bush. The Précoce de Bergthold, Early Mirabelle, and St. Etienne are all pleasant early Plums, but too small for useful cultivation.

In August we are well provided with dessert Plums; the earliest to ripen is The Czar, followed by the De Montfort, Early Transparent Gage, the Oullins Golden Gage, Denniston's Superb, Mallard, McLaugh-

lin's, Yellow Impératrice, Green Gage. The Oullins Golden Gage is sometimes placed as a market Plum, and therefore a culinary fruit. Grown on a wall it attains a very large size, and is one of the most delicious, being singularly delicate in flavour. It was imported some years since from France, and was raised, I believe, in the district of Oullins, near Lyons, in France. The tree grows rapidly and vigorously, and a specimen tree produced some years since about 10 bushels of fruit, which were sold at 9s. per sieve. This was about twenty years since; the profit derived from one tree, multiplied by 200, seemed to promise very fairly; they were planted, and in a few years the 200 trees were as large as the original, and are now capable of bearing the same quantity. These trees have never paid their expenses; the fruit is too soft for carriage, and the wood in this country never appears to be capable of ripening enough to give the necessary vigour to the bloom, and my 200 trees instead of producing, as they ought, £4 10s. per tree, will have to be destroyed to make room for other kinds. These are some of the chances of fruit growing. The dessert Plums of September are numerous. The Green Gage will not be over, and we have the Bryanstone Gage, a later variety of the Green Gage; Golden Esperen; the Purple Gage, the Jefferson, Kirke's, Violet de Galopin, Angelina Burdett, Decaisne, Reine Claude de Comte Atthems, a very fine Plum of recent introduction; Guthrie's Late Gage, Boulouf, Abricoté de Brauncau, Transparent Gage. All these are fine dessert Plums, and will certainly suffice for the dessert table during September. In October the list of dessert Plums becomes attenuated, the Late Transparent, the Reine Claude de Bavay, Golden Transparent, Coe's Golden Drop, the Blue Impératrice, Ickworth Impératrice, and Grand Duke will last during the first fortnight of this month, Late Rivers coming at the end.

Although the Plum takes rank as a dessert fruit, I think this quality mainly exists in the varieties of the Green Gages, and its real importance lies in its economic value as a culinary and preserving fruit, and here it is unsurpassed. It is very hardy, enormously productive, and forms an important article of food, and therefore always commands a leading position in the fruit markets. To obtain a good price it is important to plant those sorts which are either early or late, but it is of course inevitable that these conditions cannot always be maintained. Owing to the good fortune of my father in raising a very early fruit I have been successful in realising a good price, and the Plum which has done me yeoman's service is the Early Prolific or Early Rivers. In some years this fruit has been gathered on the 20th July, in ordinary summers the gathering commences the last week of July. The next to ripen is a seedling of my own, The Czar, which has become almost as popular as the Early Rivers. I have recently raised three early Plums, which I think will prove valuable for market. These are the Bittern, Curlew, and Heron. After The Czar I have The Sultan, a very large red Plum; then the Belle de Louvain. With this Plum the glut sets in, and the market is amply supplied with Victoria, Diamond, Mitchelson's, Belgian Purple, Prince of Wales, Prince Englebert. These are the principal midseason market Plums. The later market Plums which generally give an increase of price are Pond's Seedling, Autumn Compôte, Archduke, and the Late Orleans. I find the Early Orleans so delicate in the skin that it is difficult to pack without injury, and that noble looking fruit, Cox's Emperor, is liable to the same defect; this latter bears such quantities of heavy Plums that they rot on the tree in damp weather. The last Plum to gather from the tree is a variety from Yorkshire, this is the Wyedale. The fruit will hang until the end of November, and although very acid to the last, it is pleasant to be able to gather fresh Plums.

The Monarch, a recently introduced Plum, I believe will be a very valuable market Plum. It is ready to gather generally about the 25th of September. It is a very large purple fruit, hardy, and of excellent quality either for preserving or cooking. The Grand Duke is another late seedling; the fruit is very large, and on a wall it attains a very good flavour. I do not, however, think that it is desirable to plant it on a large scale for the orchard—the fruit is too heavy to resist the autumn gales. The Autumn Beauty or Belle de Septembre is a very valuable late Plum, and in some soils succeeds well, but I think it does not flourish in all districts.

The Mirabelle Plums are not at present grown in England for preserving, but I believe that a considerable industry exists in the neighbourhood of Metz for the preparation of the delicious preserve known as the Mirabelle de Metz. There is no reason why this industry should not be carried on in England, as the Mirabelle ripens and bears freely in this country. The fruit makes a singularly delicate preserve. During the last year or two my trees, which bear very freely, have been attacked by blackbirds, which appear to have only recently discovered

their excellence. Seedlings which I have raised from this Plum vary in a singular manner. One of the seedlings has produced a Plum resembling the Green Gage in size and flavour, rendering the original parentage of the Green Gage less obscure. Another seedling bears a small rose fruit, very pretty and ornamental.

There is, I think, a very considerable field open for drying Plums. We already possess the Impératrice, but they ripen rather too late, as I believe that for drying Plums sun heat is required as well as stove heat. Amongst my numerous seedling Plums I have discovered some which appear to me to fulfil the conditions required for drying, and as they ripen in August there will be time for the sun to assist in the process. One of these seedlings resembles exactly the Guimaraens Plum, so popular in Portugal for preserving, so that I hope some day to rival the delicious preparations of the convents. There will, I am sure, be ample room for us, and I shall not take away their business.

I may say that my soil consists of clay and strong loam lying upon a subsoil of drift clay and cretaceous gravel and sand, and that it has been trenched 2 feet deep on an average, and that previous heavy dressings of farmyard manure were applied, which has not yet been exhausted by the trees.

The abundant crops produced by the Plum and the energy required to produce the hard shells protecting the seed affect the vitality of the tree, if crops of fruit are frequently produced. It is not necessary to plant at any great distance, my own plantations are, as a rule, 9 feet row from row, and are dwarf standards. The tree is impatient of pruning, and when fruit is produced in quantity it is hardly necessary to prune at all. I, however, suppress the gross shoots, which are occasionally produced, apparently in sheer wantonness. These are dangerous, as they disturb the balance of the tree. All pruning should be done in summer or early autumn. In the severe winter of 1870, having nothing for some of my men to do, I set them to prune some of the lower branches of my trees, with the most disastrous results. Nearly every wound resulted in canker. It is a lesson which I have never forgotten.

The Kelsey Plum, which seems to be attracting some curiosity, is a Japanese variety, which has been planted to some extent in California. A correspondent to whom I wrote some time since, and who happened to be a Devonshire man, informed me that he thought it might succeed in the south and west of England, but he thought it too tender for general cultivation. It is the size of an ordinary Elruge Nectarine, with very solid flesh and indifferent flavour. It may possibly succeed as an orchard house fruit, but it remains to be seen whether it will prove a desirable acquisition. The dessert Plums attain a very high flavour when grown in pots, and they may be placed out of doors to ripen, and an annual crop can be insured. They form a very pleasant addition to the fruit garden under glass. An orchard house full of Plums alone is very ornamental, as the colours may be alternated, and fruit gathered from the beginning of July to the middle of October.

Espalier and wall trees produce remarkably fine fruit, but on some walls the tradition has arisen that the old-fashioned Green Gage is extinct. This is a mistake, arising from the fact that on old trees a few fruits have been produced which have developed to a very large and luxurious condition. The Purple Gage is also a curiously rich Plum, but is generally shy in bearing.

WINTER CUCUMBERS.

CUCUMBERS, like many other garden products, appear to be valued just in proportion to their scarcity. If by some slip of the tongue of an assistant an idea becomes settled in the kitchen that Cucumbers are scarce in the garden the kitchen people will become especially alive to their importance, and every order sent to the gardener will begin with Cucumbers. If there is one season more than another when Cucumbers are really scarce, and at times especially valued, it is during the months of December, January, and February. I have generally passed through these months tolerably comfortably by commencing preparations in good time, and thus mostly avoided any serious scarcity; and, if scarcity at times has occurred, by keeping as much as possible the knowledge of that circumstance to myself.

Cucumbers for fruiting during the winter should be planted at once, and the plants should be strong to begin with. I sow the seeds during the last week in July, and grow the plants under the influence of all the light and air they will endure, with the object of producing woody stems and medium-sized thick leaves—not large flabby foliage.

It is no use attempting the growth of winter Cucumbers unless well-heated houses are provided (I mean houses containing a suffi-

cient amount of piping to preserve a night temperature of 70° in severe weather without violently heating the pipes). That temperature may not always be required, but it is none the less necessary that the pipes should be able to produce it. Overheated pipes promote red spider, weakly growths, and deformed fruits. In addition to pipes for affording bottom heat I like a good quantity of dung and leaves, and the Cucumbers like it too. A bottom heat of 80° to 85° is a suitable temperature for the roots.

Soil, of course, is important. It should be fresh, good, and rough. Chopped turf just blackened with soot I have found suitable; if at all poor, one-third of horse droppings—old Mushroom-bed manure—may be mixed with the loam. A great bulk should not be employed at once. Commence with a small hillock for each plant, and surface-dress weekly or whenever roots protrude and ask for fresh food. Active surface roots induce healthy fruitful growth, and open—previously warmed—turfy soil and warm water secure active roots. Water must be given according to circumstances. It must at all times be sufficient, at no time excessive.

Temperature, ventilation, and atmospheric moisture are important elements in winter Cucumber culture, and not much less important is bright clean glass. A night temperature of 65° is a safe one, with just a chink for air in the top ventilators. During very severe and also dull weather the thermometer may fall to 60° at 6 A.M. The day temperature should be 5° or 6° higher by fire heat, and should reach its maximum at 9 A.M. That is important. The sun heat may rise to 80° to 85°. Watch for this, and bottle it up by early closing; it will save coals and produce green foliage (which red spiders do not appear to like), and green Cucumbers, too, which look well anywhere—on the plants or the table. As the temperature increases so let the moisture increase; this will be insured by the troughs on the pipes when the heat is from the fire alone, but with sun heat the walls and paths occasionally need damping. Syringe on favourable occasions. The water must not hang about the plants during hour after hour. One good syringing weekly is more effectual than daily dampings. Prevent red spider appearing if possible. Perfectly clear soot water is a deterrent; it is also stimulating to the plants.

Great watchfulness of the weather at night, early morning attention, cautious admittance of air, intelligent guidance of heat and moisture, are the chief essentials to success in winter Cucumber culture.—R. G.

NOTES ON EARLY ENGLISH HORTICULTURE.

(Continued from page 337.)

Not many months before that event in English history of no small importance, the revolution of 1688, Charles Cotton died in St. James's, Westminster, where he probably was sometimes resident, and may have had a house, also a garden there. It is likely, however, that the chief of his experiments in gardening were made at his abode in Derbyshire, on the banks of the far-famed Dove, the place being Beresford, and here he was visited by Isaak Walton, to whose "Complete Angler" he contributed the second part. A man evidently not wanting in genius, master of several languages (ancient and modern), a composer of poetry, and great in gardening as well as in angling. We see him in another aspect when we also view him as an officer in the Guards, and more than once mixed up in duels. A moderate sized book he published in 1675 represents the state of knowledge at that date on the subject of fruit culture, and he gives full directions, resting evidently on practice, not theory, how the various sorts of fruit trees should be planted, pruned, and cultivated; whether they yielded "stoue fruits or *pepin* fruits," as he puts it. Cotton was apparently the author of the original definition of an espalier—"a hedgerow of fruit trees against a latticed pole or stakes;" and of a centre-spalier—"a hedge of fruit trees against a wall." He descants upon the benefits of brick walls, especially in exposed localities, because they afforded warmth and shelter to the larger fruits. When trees are planted in the open ground he commends the quincunx order of planting—that is, the putting four to form a square, and one in the centre. October is the month in which he advises that young trees should be set and older trees removed, showing that one fancy of the early horticulturists had not lost its influence—*i.e.*, limiting to one month what might be done in several, or varied according to the species of tree. Cotton advises that the surface soil round fruit trees should be frequently turned over during the summer. Modern gardeners will not spare the time, but if it could be done at least occasionally many insects in their chrysalis stage would be destroyed. The use, not of nails, but of other points, formerly called "sheepshanks," is recommended by him, to which the shoots can be tied.

The close of the eighteenth century is a time which draws our

attention to the village of Chelsea—for village it then was, though now a part of the great metropolis—since it is associated with important horticultural experiments. That lengthy pile of buildings, Chelsea Barracks, which overlook the gardens of Chelsea College, is probably on the site of what we should call the home garden of Ranelagh House, but the gardens extended over many acres round, and, if Bowack is to be believed, were regarded as the finest in England, the space considered. Lord Ranelagh was of Irish descent, and a peer who gave much time to the promotion of horticulture. He had greenhouses with glass roofs (then a great novelty), and laid out his beds and walks in a manner that excited much admiration. As I previously pointed out, what were styled "greenhouses" two hundred years ago had not glass roofs, and even far on in the eighteenth century they were often without them, though they might have large side windows. It has been stated that an orangery at Woollaton Hall, near Nottingham, constructed about 1696, was the first glass-roofed house in Britain, but the matter is doubtful. A visitor, one Mr. Gibson, who during the reign of William inspected the gardens near London, tells us that Lord Ranelagh's kitchen garden was provided with seats! A remark made by another author, that he saw a part of the grounds of the Apothecaries' Company arranged in the Irish style, suggests that this particular style, whatever it might be, was introduced by Lord Ranelagh. He had in his ground a wilderness, so-called then, or what we should now call a shrubbery, which remained intact many years, giving name afterwards to "Wilderness Row." This quaint old peer would be astonished could he see the modern shrubberies and clumps of trees in the locality he once tried to beautify.

But the apothecaries' garden at Chelsea, still existent, and which was the fourth of the botanical gardens in England, is of great interest, as being far more important than its precursors in stimulating research for exotics; it also formed a centre, to which gardeners resorted to see novelties, and to inquire about methods of propagation or culture. There had been a garden at Westminster for the cultivation of medical and other plants during the middle of the seventeenth century, and in the year 1676 this place was the property of a Mrs. Gape. We should like to know whether she was a cultivator of plants, or simply the owner of the land, for the fact is very prominent and seems singular that in the early annals of horticulture the female sex scarcely figure at all, though subsequently gardening became such a favourite pursuit with ladies. However, the apothecaries purchased the collection of plants in this Westminster establishment, and they became the nucleus of their Chelsea garden, which was to receive so many exotics in after days. It would be curious to see a greenhouse of two centuries ago, but the oldest extant at Chelsea does not date as far back, though there are antiquated structures there, which tell us of a time when forcing and the nurture of plants in winter taxed seriously the resources of the gardener. According to Evelyn, in ten years "there had been obtained a large assortment of rarities, and in the autumn of 1685 he saw a conservatory of the newest design, vaulted beneath, and kept warm all the winter by a stove below, so that the windows might be opened even in hard frost. A year or two after Gibson, already mentioned, reports that Watts, keeper of the garden, had allowed much of it to fall into neglect, and though he was a man of ability he was removed from his post. This garden seems to have been the first place where an endeavour was made to have an arrangement of growing plants in which they were grouped to exhibit their natural affinities. Several new evergreens were introduced here. Probably the number growing in Britain did not exceed a dozen when William III. landed, excluding of course our few native species. It was about this date that in the London nurseries they began to raise forest trees and hedge plants by striking slips, or from seeds.

There was an increased demand for evergreens, it is observable. Owing to the prevalence of the Italian style of gardening during the seventeenth century certain species were in favour, such as the Myrtle, Bay, and Box. Myrtle was also occasionally used for hedges at Chiswick. Round part of Sir Stephen Fox's garden were hedges of this shrub, which were protected in the winter by boards. Some of the evergreens were sold at moderate prices; a nurseryman named Pearson had in 1691 abundance of Cypressess, 3 feet high, at 4d. Verspriet, a Dutchman probably, is noted by Gibson as having specimens of the *Lentiscus*, for two of which he got £40 from Sir Henry Capel of Kew. At Hoxton, then famous for its gardens, Darby had begun to obtain varieties of the Holly, and he kept specimens in books of the deciduous plants he grew. Fairchild, of the same place, introduced the Aconite and Hellebore; he studied botany, which few gardeners then did, and read a paper before the Royal Society upon the motion of sap. He was also author of the "City Gardener," published in his later years (1722), and the founder of an annual botanical sermon. His Vineyard is referred to, about 1700, as being remarkable for the Grapes it

yielded; and another famous vineyard was at Mile End, to the east of London, where Clements was very successful then with the Frontignac and White Muscadine.—J. R. S. C.

EVENTS OF THE WEEK.—To-day (Thursday) the National Chrysanthemum Society's Provincial Show at Hull, in conjunction with the local Society, will be opened in the Artillery Barracks, and a Conference will be held in the evening, at which Mr. E. C. Jukes is expected to preside. The Show will close on Friday evening. Upon the same day the International Chrysanthemum Centenary Exhibition will be opened at Edinburgh and continues until Saturday. Chorley and Stockport Shows are announced for November 22nd, and the Ghent Centenary Celebration will be opened on November 24th.

— **BIRMINGHAM SHOW.**—Our reporter telegraphs: This year's Exhibition is unquestionably the best ever held by the Society. In the chief class for cut blooms (forty-eight) the first prize of £25 is won by J. Corbett, Esq., M.P., Impney Hall, Droitwich (gardener, Mr. Parker), after a very close struggle with W. Marshall, Esq., Taunton, both having remarkably fine blooms. The latter received the second prize of £15, the third going to Colonel Wingfield (gardener, Mr. Lambert), the fourth to Sir G. Moss, the fifth to Sir R. Moon, and the sixth to Lord Heytesbury (gardener, Mr. Horsefield). Specimen plants were well shown by Mr. Cooper, gardener to the Right Hon. J. Chamberlain, Highbury, Birmingham, Sir J. Martineau being second, and F. Denning, Esq., third. Three splendid groups were arranged, the first prize one, exhibited by Mr. Cooper, being particularly fine. In the chief class for Grapes (six bunches) the Earl of Harrington was placed first, J. F. Campbell, Esq., Utttoxeter, second, and the Earl of Cork, Marston House, Frome (gardener, Mr. Iggulden), third. A report will appear.

— At the Winchester Show, on Tuesday, which was not large but very good, Mr. F. W. Flight won the Ladies' Challenge Cup for the year with forty-eight beautifully fresh and well finished blooms. He was also awarded the N.C.S. certificate for the best bloom in the Show—a magnificent example of *Etoile de Lyon*, a similar award of merit being granted to Messrs. W. & G. Drover for one of the finest stands of *Anemone* flowered ever seen. A first-class certificate was granted by the Judges (Messrs. W. Holmes and J. Wright) for a new *Anemone Pompon*, which was named *Bessie Flight*, a deep rose-coloured sport from Madame Montels, secured by the father of the lady whose name it bears. Further notes on the Show must be deferred.

— **LIVERPOOL SHOW.** which opened on Tuesday, the 19th inst., was a great success. Cut blooms, especially Japanese, were excellent, and in the chief class the first prize was won by Mr. R. Foster, gardener to S. H. Thompson, Esq. Specimen plants and groups were also good; but in the fruit classes there was some falling off. A report will appear.

— **GLASGOW AND WEST OF SCOTLAND HORTICULTURAL SOCIETY.**—Mr. Franc Gibb Dougall informs us that the Directors have decided that the spring show of the Glasgow and West of Scotland Horticultural Society will be held in the City Hall, Candleriggs, Glasgow, on Wednesday, 26th March, 1890. The autumn show will be held in the same place on Wednesday and Thursday, September 3rd and 4th, 1890.

— **THE PORTSMOUTH SHOW** appears to have been a great success. Upwards of 21,600 persons paid for admission, and 5000 children were admitted free.

— **NATIONAL ROSE SOCIETY.**—The arrangements to be submitted to the general meeting on December 4th are that the Metropolitan Exhibition be held at the Crystal Palace on Saturday, July 5th, 1890; and the provincial Show at Birmingham on Thursday, July 17th. To this latter Show silver cups, of the value of ten guineas each, have been presented by the Right Hon. Lord Calthorpe, the Right Hon. Joseph

Chamberlain, M.P., and A. H. Griffiths, Esq. The annual meeting will be held at the rooms of the Horticultural Club on Wednesday, December 4th, at 3.30 P.M., and the annual dinner at the same place at 6 P.M. The chair will be taken by the Very Rev. the Dean of Rochester, President of the Society.

— **PRESENTATION TO MR. ERNEST BENARY.**—On the 10th inst. this well known German seed merchant completed the 70th year of his age and the 50th year of his connection with the business carried on at Erfurt. His two sons made their father a present of an album containing the portraits of many of those in the United Kingdom who had done business with him for years past. Some of the leading seed firms in this country took advantage of the occasion to present Mr. Ernest Benary with a congratulatory address, which was signed by the representatives of twenty-one houses of business. The address was encircled by a very richly illuminated gold border, relieved with scrolls in beautifully toned and harmonised tints of red and blue. The arms of England and Germany in oval shields surmounted the address, and to correspond with this at the bottom was an hour glass entwined in Ivy, typifying age encircled by friendship. At the sides were two pretty bordered panels, with the dates Nov. 10, 1819, and Nov. 10, 1889. The designing throughout was most artistic.

— **TRITOMA UVARIA.**—It is not surprising that this should be commonly called the Flame Flower, as throughout September and part of October its tall handsome spikes have a grand illuminating effect in their dazzling brightness. Isolated plants are not so attractive as groups or rows, and it is in either of these forms that it is most telling. It grows best in rather a heavy rich soil, and is always finest when allowed to remain in the same place undisturbed for many years.

— **LILIUM LEITCHLINI.**—Having a number of this with other species, twelve months ago the bulbs were started in a cold pit, and in May transplanted into the open ground. They did very well indeed, and the bulbs are perfectly healthy and appear as likely to succeed in the open as many other *Liliums*. To those who do not know it, it may well be recommended, being sweet-scented, the flowers of good size, expanded, and of differing shades of spotted yellow. It is a charming companion to the various forms of *speciosum* which flower at the same time.—N.

— **THE members of the READING AND DISTRICT GARDENERS' MUTUAL IMPROVEMENT ASSOCIATION** met at the "British Workman" last week to hear a lecture from Mr. B. J. Austin, entitled "Plant-Green." There was as usual a large attendance. Mr. Wm. Lees presided. Some good specimens of *Cyclamen*, profusely flowered, were exhibited by Mr. T. Smith. A fine basket of Raspberries came from Mr. Carter, the variety being *Hornet*, and a good sample of Peas, Sutton's Latest of All, gathered from the open ground. Mr. Austin's lecture, which was illustrated with diagrams, was exceedingly interesting and instructive. The Chairman hoped the lecture would be one of a series from Mr. Austin. On the motion of Mr. Jas. Martin, seconded by Mr. Baskett, a hearty vote of thanks was accorded Mr. Austin for his able lecture.

— **A FINE CAMELLIA.**—"On-looker's" note, referring to the fine plant, or rather tree, at The Henburs (see page 382) reminds me of a very fine tree I have seen in the handsome conservatory in the gardens at Balrath House, Kells, Co. Meath. It is four years since I saw it, but I should imagine it is as large as the specimen mentioned by "On-looker" by this time. If my memory serves me truly the tree at Balrath is about forty years old. Mr. Ramsay, who is now steward there, was about that time acting in the capacity of steward and gardener, and either purchased or grafted the plant about the year 1850. Perhaps Mr. Swift, the present head gardener, will kindly furnish the dimensions of the specimen, and correct me if I am in error as to its age, &c. The tree is planted out, and I believe the variety is *alba plena*.—HANDY ANDY.

— **SOUVENIR DE LA MALMAISON CARNATIONS.**—These have risen into very great popularity within the past two or three years. They are not, of course, any larger or more Clove scented than they were, but since it has been realised that a large flower may be employed for all sorts of decorative purposes—personal and otherwise—without one being considered a barbarian, these, the grandest of all Carnations, have taken their rightful place. I think the most beautiful of the trio under cultivation is the pink or rose variety. There are said to be two quite

distinct shades of this grown, one darker than the other, but I know cultivation has much to do in determining the particular degree of shade, light or dark, which this variety assumes, and if a very dark form is in existence it is strange it is kept so long out of the market. The Blush, or original "Malmaison," though not so telling, is also very fine. The third variety is that named Lady Middleton, which is the pink sort with blush stripes. This is considered rather tender and more difficult to grow than the others, but we have found it quite impossible to distinguish from the others when not in flower. These again run up to the same size, many of them 5 inches across. I have just reckoned the number of other varieties I have bought, and these amount to another five besides the above, but not one of them at all like the real "Simon Pure."—B.

— **ROYAL METEOROLOGICAL SOCIETY.**—At the ordinary meeting of the Society, held at 25, Great George Street, Westminster, on Wednesday, the 20th inst., at 7 P.M., the following papers were read:—"Second Report of the Thunderstorm Committee—Distribution of Thunderstorms over England and Wales, 1871-1887," by William Marriott, F.R.Met.Soc.; "On the Change of Temperature which accompanies Thunderstorms in Southern England," by G. M. Whipple, B.Sc., F.R.Met.Soc.; "Note on the Appearance of St. Elmo's Fire at Walton-on-the-Naze, Sept. 3rd, 1889," by W. H. Dines, B.A., F.R.Met.Soc.; "Notes on Cirrus Formation," by H. Helm Clayton; "A Comparison between the Jordan and the Campbell-Stokes Sunshine Records," by F. C. Bayard, LL.M., F.R.Met.Soc.; "Sunshine," by A. B. MacDowall; "On Climatological Observations at Ballyboley, Co. Antrim," by Prof. S. A. Hill, B.Sc., F.R.Met.Soc.

— **MR. MALLENDER** sends the following SUMMARY OF METEOROLOGICAL OBSERVATIONS AT HODSOCK PRIORY, WORKSOP, NOTTS, FOR OCTOBER:—Mean temperature of month, 46.5°. Maximum on the 10th, 58.0°; minimum on the 15th, 29.2°; maximum in the sun on the 17th, 103.7°; minimum on the grass on the 15th, 25.1°. Mean temperature of the air at 9 A.M., 46.2°; mean temperature of the soil 1 foot deep, 48.9°. Nights below 32° in shade three, on grass fourteen. Total duration of sunshine in month forty-three hours, or 13 per cent. of possible duration. We had ten sunless days. Total rainfall 3.27 inches. Rain fell on twenty-three days. Average velocity of wind, 8.7 miles per hour; velocity exceeded 400 miles on three days, and fell short of 100 miles on nine days. Approximate averages for October:—Mean temperature, 48.2°; sunshine, eighty-four hours; rainfall, 2.84 inches. A very dull and damp month, rather cold, wet, and calm; constant showery weather, but without any heavy falls, very few frosts, but cold days.

— **LECTURE BY DR. SORBY.**—Under the auspices of the Sheffield Floral and Horticultural Society a lecture was delivered in the Committee room of the Montgomery Hall on November 6th by Dr. H. C. Sorby, LL.D., F.R.S., on "Weather Charts and Storm Warnings." Sir Henry Watson, President of the Society, occupied the chair, and said Dr. Sorby was so well known in scientific circles, not only in London but in the various towns in the north of Europe, that it was surely unnecessary to introduce him to the people of Sheffield. Dr. Sorby had been born in Sheffield, lived in it all his life, and was an honour to the town. They all knew how interesting he could make his lectures, and with what thoroughness he investigated the subjects he undertook to lecture upon. Knowing these facts he was sure no one would leave that room without adding to their store of learning. The lecturer had a very cordial reception, and commenced the lecture by giving an account of the constitution of the atmosphere surrounding the earth, and explaining the effect the sun had upon it, both by producing disturbance in the form of wind, and by bringing about the deposit of rain. He then fully described cyclones, and showed that the character of the weather in England depended upon the course of those cyclones. If they moved to the north of our country mild weather resulted, but if they moved towards the south the weather became cooler. Opposed to the action of these cyclones were the winds generally known as anti-cyclones, so-called because their peculiarities were opposite to those of cyclones. Cyclones often moved rapidly, but anti-cyclones moved slowly, and were accompanied by dry and calm weather. It was very difficult to foretell the weather in England, because almost all the atmospheric disturbances moved from the south-west to the north-east, and often advanced to the British Isles before there was time to detect their presence. If it were possible to have several stations out in the Atlantic Ocean the prediction of the weather would be much easier and more satisfactory, but with the knowledge they now had, and under the present conditions, it was possible to judge pretty

accurately what kind of weather was to be expected. The lecture was fully illustrated by means of charts, and drawings on the black board.

PLANTING FRUIT TREES—LIME.

LAST season on removing some Pear trees the effects of lime or mortar refuse came very favourably under my notice, and the present being an opportune time I give it for what it may be worth. Whatever may have been the object of the planter it certainly had the effect of thoroughly preventing the roots from penetrating the layer, which was about 6 inches thick, spread over a yard square, and at about 2 feet deep. The demolition of some old buildings caused the accumulation of a good quantity of the mortar refuse, and in the course of planting operations this was used rather freely in the sites prepared for the trees. Its effect was so marked that on a trench being dug round and the soil worked off with a fork to within reasonable distance of the stem, the tree could be easily overturned without the usual undermining; and the weight of the crop in one instance last year was such as to require support of the tree against the force of the wind; the tree, a pyramid, being about 8 feet high. Singular, too, was the fact that although the summer of last year was so wet the lime and soil immediately above it were dry to a degree that the spade could scarcely make an impression, and the grubber was found a very useful implement for hastening the work. From the fact of deep root action being prevented, the crops have been more regular than is the case when trees are necessarily subjected to root pruning, and the labour involved in making this provision would be well repaid, even if the required material had to be procured by purchase.—W. S., *Frome*.

VARIOUS NOTES.

EUCHARISES.

I THINK "M. D." is not very much out in considering the bad condition of so many *Eucharises* as the result of overwatering. I had some in a very bad state some two years ago, said to be the result of mite; but as the plants have done excellently since I restored them to health the same season, and I have further had an inkling that all might not have been right with regard to watering, I have begun to think that bad treatment has been at the bottom of the mischief, at least in our own case. The best *Eucharises* I ever saw are in gardens where perhaps one or two plants are cultivated in mixed collections of stove plants, and where the flowers are taken just as they come naturally.

LIFTING GLADIOLUS.

Mr. Murphy is right in lifting early ripened *Gladiolus* before they start making young roots. Last year and this I lifted much earlier than usual, the great bulk having been lifted in the second week of October, some earlier and a few later. None of the leaves was yellow, some being quite green. Instead of placing them under cover I have both seasons left the whole of them lying on the open ground, where the corms are exposed to all kinds of weather save frost. They do not die yellow so rapidly, as the cool damp nights preserve a good supply of moisture. Corms which have not finished actually increase in size just as spikes open when left on the ground at this season. The cormlets I leave on the old roots until spring; I think they are safer there. As to *Lemoine's* hybrids I also lift these, but some left in the ground by mistake last year came up all right this; but other varieties do the same. I think if these are to be well grown they also must be lifted and replanted every year.

For increasing stock Mr. Murphy ought to try cutting up the large corms. If carefully performed, and the corms well ripened, as many as three to five pieces can safely be secured. A medium-sized corm is much to be preferred to one of large size, as these do not, as a rule, produce a greater number of buds than two, while the former almost invariably may be cut into four.—B.

CATCHING AND KEEPING BULLFINCHES.

MR. M. DAVIDSON, on page 381, asks me to give particulars on this subject. To do justice to the matter would require considerable time and space as well as engravings. I have caught them in bat-fowling nets from thick hedges at night, with bird lime, and hundreds in trap cages. The latter mode I prefer. There is a great difference in trap cages, some of which the birds fear and will not enter, or very seldom. What I use I make to suit my fancy, and are the most practical I have met with, and here, I think, in a

great measure lies my success. I have still a better one "in my head," which I may carry out in the garden before long, when I have more leisure.

Mr. Davidson will probably get a trap cage at a bird dealer's without the expense of sending away; if not, he will find some advertised under "Appliances" in *Poultry*. I have not seen them, therefore cannot speak as to their adaptability. If not painted I would recommend at least two coats of green paint both to wires and woodwork for two reasons—protection, and to give as natural an appearance to the birds as possible. When thoroughly dry and the paint is hardened—this is important, as the birds are apt to peck it off or rub it off with their bills and get poisoned—put in your call-bird, which should, if possible, be one accustomed to captivity. I use one caught two years ago, because they become very docile and do not flutter like a new bird. The drinking tins are also painted green to take off the brightness so as not to frighten the wild ones. Hang the cage against a wall out of the reach of cats in a quiet place; my most successful spot is near an Apple tree, into which a wild bird readily comes at this season to the call of the decoy.

The trap part of the cage should be baited with Blackberries in bunches, and if a little Lettuce seed is sprinkled in so much the better. I carry a box of it in my pocket at this season. Having caught a bird it should be taken out as carefully as possible, as they are naturally terribly frightened. These birds should be first placed in a cage with wires on one side only, and they should be shallow, 6 or 8 inches deep; water may be placed in a shallow tin inside the cage at first, or many will die from not having the notion of getting at it if put outside. Feed on hemp and canary seed. If they take to this they are soon all right, but they must be watched, and if they do not place in some Blackberries or Privet berries, of which they are very fond, later in the season. In a day or two they will be reconciled, and may be taken out of the low cage and turned in a large stock cage or an aviary, always giving plenty of water for bathing and drinking. A handful of groundsel thrown in occasionally will be much appreciated, and of course they require rough grit. It is a very pretty sight to see a score or so, as I have at present, with their handsome red breasts.

There is always a demand for these birds for pets as cage birds, and they are readily disposed of to bird dealers in towns. Many a country cottager might pay his rent with a little insight into this matter, which I have repeatedly pointed out, and have given practical illustrations of how to carry it out at horticultural shows, besides freeing a neighbourhood of a universal pest in the spring at the fruit bloom.

I gave particulars as to the food of Bullfinches in a wild state for most of the year in the *Journal* some years ago. As there are many new readers perhaps it would be worth a reprint. Good bunches of Blackberries should now be procured and kept until food becomes scarce in the fields later on, for baiting trap cages, as a bird soon clears out all when shut in. If I have not made all plain I will give any further information. Up to the present I have taken twenty-two birds this autumn against twenty-three all last winter.—J. HAM.

THE WEATHER.

So far November has been singularly mild, and we have got half through without the thermometer once going below the freezing point—32° Fahr. Several nights I have gone out in my garden, where I have a hinged framework over my outdoor wall Chrysanthemums, at 10 P.M., and the thermometer stood at 55°. If this could always be guaranteed no one would house their plants. On the other hand the atmosphere has been saturated with moisture.

DAMPING OF BLOOMS.

This mild weather and atmospheric moisture naturally lead to damping of blooms, but it must be distinctly noted the damping is only noticed indoors, and is not so conspicuous there when there is a warm buoyant atmosphere, not much above or below 60°. At least that is my experience, as I keep a few dozen pots inside for experiment, the vast majority of my pot Chrysanthemums being in front of and forming a sloping bank with my wall plants.

As I have already intimated, if Chrysanthemums could be grown wholly in the open air there would be no damping. Then it follows the more nearly we can in Art approach the perfection of Nature the nearer we approach success. At the same time in manufacturing towns

thickly populated, it is no remedy to throw open the ventilators, and admit a moist, murky, and smoke and soot-laden atmosphere. In case of pot plants grown on the large bloom system, as distinguished from decorative or for cutting, the best precaution against damping is thorough ripening, and exposure of the plants in the summer and autumn. Excessive stimulants, especially sulphate of ammonia, lead to damping.

GOOD NEW VARIETIES.

I am going to the Waterford district exhibition, and shall learn further on this head; but here in this locality we have found Sunflower, Mrs. J. Wright, Avalanche, Edwin Molyneux, Mr. and Mrs. H. Cannell, Agnes Flight, Amy Furze, Theodore Bullier, and Florence Percy first-rate exhibition large flowers when taken on the crown bud. Terminal buds of the above and the following with me are almost useless:—Japanese: Mr. Garner, Mrs. F. Thompson, W. H. Burbidge, Mons. Bernard, Rose Beauty, Charlie Sharman, Gladiator, Yokohama Beauty, and Bomhardier. Anatole Cordonnier promises well, but curiously enough there is not a single good bloom of Belle Paule in any direction here. Lady Dorothy, James Weston, Goldfinder (late), and Ralph Brocklebank late but promising, Nelson and Sabine (large Anemones) are not large with me. On the whole the blooms are rather above the average in the general collections.—W. J. MURPHY, *Clonmel*.

MRS. MARSHAM AND ELAINE.

I CAN assure "Chrysanthemum" (page 387) that Mrs. Marsham and Elaine are synonymous. When the supposed improved Elaine Mrs. Marsham was first sent out, I procured a cutting at a good price. I thought if we had really an improvement on Elaine, as stated, that it would be an acquisition worth looking after. The cutting was rooted with other varieties and well cared for, as most new varieties are at first. When the flowering time arrived I could see that I had been duped. All there was to distinguish Mrs. Marsham from Elaine was the label in the pot. That is one of the many instances in which the National Society has been of great benefit.—A CHRYSANTHEMUM GROWER.

MRS. CARTER.

MESSRS. J. CARTER & Co. have had an interesting display of Chrysanthemums this season at their Perry Vale Nurseries, well representing all the best of the old and new varieties. Some of the novelties were exhibited at the Chiswick Conference on November 5th, amongst them being blooms of the variety Mrs. Carter, of which one is depicted in the woodcut (fig. 56). This is a pretty and graceful Japanese, with exceedingly fine threadlike florets of a soft clear straw colour. It will probably prove useful for cutting purposes, as light flowers like these are admirable for arranging in vases.

A BLOOM HOLDER

IN the illustration of a Chrysanthemum bloom holder, page 419 in last week's *Journal*, is shown a modified form of my holder for cut flowers (patented in 1884). I enclose a sample, the same as is used for Chrysanthemums; also a tube which is made rather deep so as to allow the blooms to be raised a good height above the board, without anything being seen except the stem. The coils at the top of the support can be raised or lowered to suit any bloom.—H. FOSTER, *Watchmaker, Ashford, Kent*.

[The sample sent is very similar to the one figured, except that there is a double coil at the base of the bent wire in the tube, and a horizontal ring to hold the stem near the mouth of the tube.]

CHRYSANTHEMUM SHOWS.

PEMBROKESHIRE.—NOVEMBER 12TH.

THE fourth annual Exhibition of this Society was held in the Market Hall, Pembroke, on the 12th inst., and proved in every way most satisfactory. Although a young Society, it has become firmly established, and the Show is one of the best held in South Wales. The majority of the exhibits would compare most favourably with those of larger provincial societies, and nowhere have we seen cottagers and amateurs show better produce, both in plants and cut flowers. The arrangement throughout was admirable, reflecting much credit on the courteous Hon. Sec., Mr. Treweeks, and those of the Committee working with him.

Plants.—For groups of the largest size arranged for effect, quality also to be considered, Mr. French, gardener to Colonel Saurin, Orielson, Pembroke, was a very easy first with dwarf plants, tastefully arranged, and carrying extra fine flowers. This group was one of the features of the Exhibition, and was much admired. Mr. Crichton, gardener to Colonel Lamhton, Brownslade, was second. Many good trained plants were staged. For three Japanese, Mr. Dumble, gardener to Sir Charles Philips, Picton Castle, Haverfordwest, was first, having freely flowered plants of Bouquet Fait, La Nympe, and Val d'Andorre. Second, Mr. French. Mr. Dumble was also first for three incurved or reflexed varieties; but for a single specimen Japanese, Mr. French was a good first with a superbly flowered plant of Avalanche, and this in addition was awarded the National Chrysanthemum Society's silver medal as the best plant in the Show. Amateurs exhibited strongly, six competitors staging good groups. Splendid plants and cut blooms were also good. For the former Mr. Croft was first, Mrs. Rowe being a good second.

Cut Blooms.—With thirty-six blooms, for which a special prize was given by Sir C. Phillips, Mr. Dumble was easily first, having decidedly the best flowers in the Show. They comprised (Japs) Baronne de

Prailly, Fair Maid of Guernsey, Madame C. Audiguier, E. Molyneux, Mr. H. Cannell, Lady Lawrence, Carew Underwood, Boule d'Or, Triomphe de la rue des Châlets, Stanstead White, Belle Paule, Meg Merrilies, Sunflower, Val d'Andorre, Ralph Brocklebank, and Elaine. Incurved: Golden Empress, Alfred Salter, Queen of England, Mrs. Heale, John Salter, Jeanne d'Arc, Empress Eugénie, Empress of India, Golden Empress (very fine, awarded a medal as the best bloom in the Show), Princess Teck, Prince Alfred, Novelty, Mr. Bunn, Princess of Wales, Lord Alcester, Barbara, and Refulgens. The same exhibitor was also first for twenty-four blooms; Mr. French being a close second; third, Mr. Crichton. The same exhibitors took the prizes for twelve blooms. Many other classes, too numerous to mention, were well filled. Among the successful competitors the following obtained several first prizes:—Mr. Stephens, Mrs. Rowe, Mr. Skyrme, Mr. Croft, and Miss Elsdon. Fruit and vegetables made in this section a good display, and collectively the Exhibition was a most successful one.

LEEDS.—NOVEMBER 12TH AND 13TH.

THIS Show, which was the finest ever seen in Leeds, was held in the Town Hall. For several years past the Chrysanthemum Show has been held under the auspices of the Leeds Horticultural Society, but had failed to meet with success, the deficit in the finances after last year's show being considerable. Under these circumstances the Committee met some ten weeks since and decided they could not again undertake the responsibility of forming a show. The members of the Leeds Paxton Society at once held a meeting, and in a most spirited manner decided upon taking up the matter. A guarantee fund was initiated and liberally responded to, upwards of thirty, we are told, of those present becoming guarantors of 1 guinea each. Dates were fixed upon, the Town Hall taken, and a vigorous canvas of the Leeds residents for subscriptions commenced, with the result that upwards of £120 was collected, thus insuring the success of the Show, financially speaking, before the doors were opened to the public. The Leeds Paxton Society consists of about eighty members—gentlemen's gardeners and amateurs—who meet fortnightly for the object of reading and discussing papers upon horticultural topics, and their above remarkable success in carrying out a first-class show upon so short a notice serves to prove what may be done by a body of earnest men who are united in effort. There was a large attendance of subscribers present at the opening ceremony, which was undertaken by the Mayor (Ald. Emsley), who was accompanied by the Mayoress, and assisted by the ex-Mayor (Ald. Ward), Sir Edwin Grant, Sir George Morrison, Ald. Boothroyd, and other gentlemen.

The general appearance of the Show on entering the hall was very fine. Immediately facing the visitor were long rows of cross tables containing the numerous entries in the open classes for cut blooms, whilst down the centre, and also at the two sides, was a fine display of groups arranged for effect and of specimen plants. Facing the large orchestra was a row of tables filled with a fine display of fruit, whilst the orchestra itself was furnished with a competitive display of large specimen foliage plants and Ferns.

In the open class for thirty-six cut blooms, eighteen each incurved and Japanese, thirteen competitors staged flowers, the general quality of which was very high. The first prize was secured by Mr. P. B. air, Trent-ham Hall Gardens, Staffs, with a very superior collection, the incurved flowers being large and finely finished, whilst the Japanese also were very large and brightly coloured. The flowers shown in these stands were:—Incurved, back row: Lord Alcester, Alfred Salter, Empress of India, Bronze Queen (very fine), Golden Empress, and Empress of India. Middle row: Violet Tomlin (extra good), Emily Dale, Golden Empress, Mrs. Heale, Lord Wolseley, and Queen of England. Front row: Miss Haggas, H. Shocsmith, Beverley, Mr. Brunlees, Princess of Wales, and Jardin des Plantes. In Japanese the varieties were:—Back row: Stanstead White (fine), Edwin Molyneux, Etoile de Lyon, Meg Merrilies, Boule d'Or, and Stanstead White. Second row: Madame C. Audiguier, Avalanche, Criterion, Belle Paule (good), Fair Maid of Guernsey, and Val d'Andorre. Front row: Sunflower, Sarah Owen, Fimbriatum, Jeanne Délaux, Ralph Brocklebank, and Avalanche. Closely following the first prize collection were very nearly equally meritorious stands from four or five competitors, and considerable time was taken by the Judges in deciding as to the second and third, those shown by Mr. Leadbetter, gardener to J. Wilson, Esq., Tranby Croft, Hull, ultimately securing second place; whilst Mr. W. Midgley, Banorfield, Bingley, Yorks, was placed third.

In the open class for twelve incurved blooms Mr. Midgley was first with—Back row: Empress of India, Lord Alcester, Golden Empress, and Queen of England. Second row: Empress Eugénie, Hero of Stoke Newington, Mrs. Heale, and Mr. Bunn. Front row: Lady Hardinge, John Salter, Mrs. Shipman, and White Formosa. The second prize went to Mr. T. Ketchell, gardener to H. Simpson, Esq., Ackworth; third, Mr. Wm. Boston, Bedale, Yorks. Twelve Japanese, distinct, open class, brought three competitors, Mr. W. Pearson, Knottingley Hall Gardens, being first; Mr. Midgley second, and Mr. Boston third. The flowers on Mr. Pearson's stand were—Back row: Boule d'Or, Stanstead White, Madame J. Laing, and Gloriosum. Second row: Val d'Andorre, Comte de Germiny, Edouard Audiguier, and Fair Maid of Guernsey. Front row: Elaine, Marguerite Marrouch, Mdle. Lacroix, and Martha Harding.

Class N (open) for twelve Chrysanthemums, three incurved, three Japanese, three reflexed, and three large flowering Anemones, was a very

good one, and brought four competitors. The first prize was taken with a very bright and good stand by Mt. W. Grix, gardener to Sir Jas. Kitson, Bart., Gledhow Hall, Leeds.

Miscellaneous flowers, Camellias, bouquets, sprays, and coat-flowers were all well shown and filled a large table amongst the open classes. Fruits also, especially Grapes, were of a high order of merit and well shown. Mr. Midgley obtained first prize in each case for two bunches of black and two bunches of white Grapes. Some very tasteful and pleasing groups of mixed Chrysanthemums and foliage plants occupied the centre of the hall, the first prize being taken by Mr. Frankland, gardener to J. Barron, Esq., M.P., Chapel Allerton Hall; second, Mr. Townsend; third, Mr. W. J. Dixon. Groups of Chrysanthemums were also well shown by Mr. Boston, Bedale; Mr. Moore, Allerton Hall Gardens; and Mr. Eastwood, gardener to Mrs. Tetley, Westwood, Leeds, the first, second, and third being awarded in the order given.

The exhibits not for competition were numerous and good. Messrs.

FIG. 56.—CHRYSANTHEMUM MRS. CARTER.

Clibran, Altrincham, had a large stand of sixty blooms. Mr. T. B. Morton, Mowden Bridge Nursery, Darlington, had a large stand of fine blooms, mostly new Japanese. Messrs. Dickson, Brown & Tait of Manchester showed an exceedingly fine bank of well-grown Cyclamens. Mr. J. Carter, nurseryman, Keighley, had a fine stand of cut blooms of Primulas, double and single.

A word of commendation should be given to the officials and the hard-working Committee who so successfully carried this fine Show to a termination, and especial mention is due of the efficient work done by Mr. William Grix, Chairman of Committee, and Mr. Thos. Bonsal, Elmet Hall Gardens, Leeds, the courteous Secretary.

WELLS.—NOVEMBER 12TH AND 13TH.

Few societies have made better progress that has been observed at Wells. The Exhibition is not a very extensive display. There is not room for it in fact, but in every department the competition was close

and good, many of the exhibits being capable of winning prizes at more pretentious shows. Mr. A. G. Andrews is the Hon. Secretary, and this gentleman is always ably assisted by the Hon. Treasurer, Mr. Robert Isgar, and an efficient Committee, who strive to make the Show a success in every way. The Exhibition was exceedingly well supported, and the Society is in a very flourishing condition.

The great feature in these shows is always to be found in the groups, notably those to occupy a space 8 feet by 4 feet, and to consist largely of Chrysanthemums. There were fewer of these than usual, but those in competition were remarkably good. Mr. J. B. Payne, gardener to the Lord Bishop of Bath and Wells, was rightly awarded the first prize, his well arranged group comprising grandly flowered Golden Dragon, Mrs. Wheeler, Fimbriatum, Avalanche, Princess of Wales, and other Chrysanthemums, and very fine Poinsettias, Epiphyllums, Azaleas, Eucharises, and other flowering plants, as well as Palms and Ferns. Mr. J. Wilkinson, gardener to C. C. Tudway, Esq., was a close second, his Chrysanthemums being very good, while Mr. G. Stokes, gardener to Mrs. Gandel, was third. Creditable groups were also arranged by amateurs. Mr. W. Potter, gardener to A. Colson, Esq., Glastonbury, was the principal exhibitor of trained plants, being first for six incurved and also for six Japanese varieties. Mr. Chislett, gardener to Mrs. Rees Mogg, Glastonbury, was also a successful exhibitor of trained plants, another prizewinner being found in Mr. E. Stokes. Mr. Young, gardener to W. S. Hodgkinson, Esq., was awarded two first prizes for fine foliage plants, Messrs. Wilkinson and J. B. Payne also being successful in the same classes. A fine lot of Primulas were shown, both single and double flowering being unusually good. Mr. Payne was first for doubles and second for singles, and Mr. Wilkinson first for singles and second for doubles.

There were scarcely so many cut blooms as last year, and on all sides complaints were heard of the best being over. In the principal class, that for twelve incurved and twelve Japanese varieties, Mr. Wilkinson took the lead, his incurved being especially good. They consisted of Alfred Salter, Empress of India, Golden Empress, Queen of England, Jeanne d'Arc, Violet Tomlin, and Miss M. A. Haggas (both very good), Princess Beatrice, Cherub, Mrs. Heale, Empress Eugénie, and Golden Queen of England. The Japanese were also highly creditable, the varieties being Boule d'Or, Pelican, Baronne de Prailly, Ralph Brocklebank, Meg Merrilies, Mrs. Cannell, Belle Paule, J. Délaux, Avalanche, E. Molyneux, and Triomphe de la rue des Châlets. Mr. J. B. Payne was a very good second, his Japanese varieties being decidedly the best. Among these were very fine blooms of Ralph Brocklebank, Avalanche, Condor, Sunflower, Mrs. J. Wright, and Golden Dragon. The third prize went to Mr. W. A. McKenzie, gardener to A. S. Somerville, Esq., who also exhibited creditably. Mr. Wilkinson was well first, Mr. Payne second, and Mr. McKenzie third for twelve incurved varieties, an extra prize being awarded to Mr. R. P. Phillips, gardener to John Bailly, Esq., Frome.

The best twelve Japanese varieties were staged by Mr. J. B. Payne, whose stand contained very fine blooms of Avalanche, Golden Dragon, Ralph Brocklebank, and Sunflower. Mr. Wilkinson was a good second, and Mr. E. Stokes third. Mr. Wilkinson was also first with Anemone-flowered varieties, and Mr. Payne a close second. The best represented varieties were Fabian de Médiana, Sœur Dorothee Souille, Lady Margaret, Madame Berthe Pigny, Minnie Chate, Cincinnati, and Duchess of Edinburgh. Mr. Payne was first, and Mr. McKenzie second for Pompons. The principal prizewinners for vases of Chrysanthemums were Mrs. Tudway and Miss Tyte, and the ladies also made a most effective display with vases and baskets of autumn foliage, fruit, and Grasses. A bouquet composed entirely of Marie Louise Violets and greenery was very beautiful. It was shown, not for competition, by Messrs. Mogford & Son.

A tempting display of fruit was arranged, though the Grapes were scarcely so good as usual. With any black variety of the latter Mr. Wilkinson was first, Mr. R. P. Phillips second, and Mr. Payne third, all showing Alicante creditably. Mr. Wilkinson was also first with Muscat of Alexandria, Mr. Payne being second, and Mr. Humphries third. Mr. Wilkinson had a grand dish of Doyenné du Comice Pear, and was first in the class for one dessert variety, Mr. J. Everett being second with very fine fruit of Beurré Diel. The most successful in the Apple classes were Messrs. Wilkinson, Payne, Phillips, and B. Taylor. Messrs. Brown staged a large and well grown collection of fruit, not for competition, these including Apples, Pears, Plums, Medlars, and Tomatoes.

BOURNEMOUTH.—NOVEMBER 13TH.

THE Bournemouth express from Waterloo Station is one of the famous trains in the south of England, and its destination is one of the most beautiful and salubrious seaside resorts in the kingdom. There is plenty of room to breathe at Bournemouth—ozone from the sea, and the health-giving aroma of the Pine woods from the land. Villas are attractive, hotels superior, roads and drives picturesque, while trees abound everywhere. No wonder at the increasing number of visitors, also of affluent residents, and no wonder, therefore, there should be a Chrysanthemum Show.

The Bournemouth and District Chrysanthemum Society was established three years ago, or at least the Exhibition to be noticed is the third of the series. It is under the immediate patronage of Her Royal Highness the Princess Christian, and the President is C. E. Baring Young, Esq., M.P., who opened the Show, and takes deep interest in the welfare of the Society. The Exhibition was in every respect markedly superior to that of last year, and was worthy of the great numbers of visitors

who attended, nearly £70 being taken the first day. The Committee and Secretaries, Messrs. C. Brown and J. Spong, worked assiduously in making everything agreeable and the Show a gratifying success.

In the open class a silver challenge cup, value £8 8s., and £3, was offered for thirty-six cut blooms, eighteen to be incurved and eighteen Japanese, not more than two of one variety. The cup was offered by the President, and the money by the Society, with £2 and £1 as second and third. Four stands were put up for competition, Messrs. W. & G. Drover being successful. Mr. G. Garner, gardener to Mrs. Braddyll, was second; and Mr. T. K. Ingram, nurseryman, third. Messrs. Drover's stand was very good indeed. The incurved were better than those in the second prize stand, and the Japanese in the second were better than those in the first, being fresher, larger blooms. The contest between the two was very close. The first prize stand contained splendid blooms of the following varieties, reading from the left hand:—Japanese—Back row: Etoile de Lyon, Boule d'Or, E. Molyneux, Gloriosum, Carew Underwood, M. J. M. Pigny. Middle row: Triomphe de la rue des Châlets, M. Bernard, M. J. M. Pigny, E. Molyneux, M. Bernard, Ralph Brocklebank. Front row: Madame Baco, Jeanne Délaux, Gloriosum, Jeanne Délaux, Mdlle. Lacroix, and Madame Baco. Incurved—Back row: Golden Queen of England, Lord Alcester, Lord Alcester, Empress of India, Golden Queen of England, Empress of India. Middle row: Lord Wolseley, Queen of England, Alfred Salter, Golden Empress, Queen of England, Golden Empress. Front row: Mrs. N. Davis, Hero of Stoke Newington, Princess of Teck, Charles Gibson, Mrs. N. Davis, and Princess of Teck. The best blooms in the second stand were Empress of India, Golden Empress, Queen of England, Alfred Salter, Empress Eugénie, Barbara, Boule d'Or, E. Molyneux, M. Bernard, Japonais, Criterion, and Jeanne Délaux.

In Class 3 (open) Messrs. W. & G. Drover were again first with the following twelve incurved:—Queen of England, Golden Queen of England, Lord Alcester, Empress of India, Lord Wolseley, Alfred Salter, C. Gibson, Golden Empress, Mrs. N. Davis, Barbara, Princess of Teck, and Nonpareil, Messrs. G. Garner and T. K. Ingram being second and third. In Class 2 (open), twelve Japanese, Mr. G. Garner was placed first with fresh brightly coloured examples of Meg Merrilies, Criterion, Avalanche, E. Molyneux, Comte de Germiny, M. J. M. Pigny, Mdlle. C. Audiguier, Fair Maid of Guernsey, Val d'Andorre, Madame Baco, Golden Dragon, and Jeanne Délaux. Messrs. W. & G. Drover and G. Read, Esq. (gardener, Mr. J. Chalk) were second and third respectively.

In the local class for twelve incurved, Messrs. T. K. Ingram, G. Garner, and S. Gould, gardener to Mrs. Dawson Damer, were first, second, and third in the order named; the same exhibitors winning in a little different order with twelve Japanese distinct. For six incurved, distinct, T. Head, gardener to General Stuart, was first, and for six distinct Japanese, F. J. Ellis, gardener to W. Henderson, Esq., was first. Reflexed and Anemone varieties were well represented.

Messrs. G. Watts & Son secured the silver cup, value £5, offered by the Society for the best group of plants, all Chrysanthemums, arranged in a space of 60 feet, quality and arrangement to be the leading features. The group well deserved the honour awarded to it. The colours were well blended, and the plants arranged without overcrowding. Altogether the group was a most meritorious one. Mr. T. K. Ingram was placed second, and Mr. H. J. Ellis and Mr. J. J. Swaffield equal thirds. Other good groups were well shown by G. Biles, J. James, gardener to W. Richardson, Esq., and J. Bush, gardener to Lady Wimborne. In the cut bloom classes, open to single-handed gardeners, Messrs. W. J. Ward, M. H. Dibben, and M. R. Legg were the most successful. Classes for table plants and Primulas were well filled. Mr. G. Garner had the best bouquet, Mr. J. Hobbs, gardener to H. Reeve, Esq., the best basket of Chrysanthemums, and Messrs. May & Co., florists, the best sprays and buttonholes. Messrs. G. Watts & Son and J. J. Swaffield had, not for competition, good groups of flowering and foliage plants. Mr. W. Parsons, gardener to Major-General Hutchinson, contributed a splendid group of Orchids in flower.

Fruit and vegetables were of good quality. For Grapes and collections of eight and six varieties of vegetables, Mr. G. Garner was first, W. Earp first for dessert Apples, and J. Menzies first for Pears. Some very good produce was staged by the cottagers; especially fine were the samples of Potatoes. This Society encourages gardening amongst the cottagers, and their exhibits show plainly that the Society is appreciated by them. Very fine weather prevailed, and visitors to the Show were numerous.

WESTON-SUPER-MARE.—NOVEMBER 13TH.

IN some respects the Show under notice was decidedly the best of the series held at Weston-super-Mare, and, what is also most satisfactory, was remarkably well supported, the Victoria Hall being inconveniently crowded at a comparatively early part of the day. Here we find a Committee largely composed of gardeners and gentlemen interested in the welfare of the town working well together, one section readily admitting that the other does excellent work. Messrs. W. H. Vanes and S. Lewis are the Honorary Secretaries, and two more obliging or efficient gentlemen could not well be found for the purpose.

It is in the plant classes where this Show more than holds its own with other rivals in the district, the competition in every case being most keen, while not a rubbishy exhibit was to be seen. The best six dwarf-trained plants of large-flowering varieties were staged by Mr. W. Brooks, among these being very good specimens of Mr. Glenney, Mrs. G. Rundle, and Guernsey Nugget. Mr. C. Holland, gardener to W. Ash, Esq., was a close second. For four varieties Mr. H. Lambert was first, having very freely flowered, not formally trained, plants of popular

sorts. Mr. W. Duffurn, gardener to Donald Cox, Esq., was a good second. Mr. C. Holland was well first with six Japanese varieties, having well trained, beautifully flowered specimens of Bertie Rendatler, Bouquet Fait, Margot, Fair Maid of Guernsey, Source d'Or, and Hiver Fleuri. Mr. W. Brooks was a close second. The best four Japanese varieties were shown by Mr. W. Duffurn, who has done well at a first attempt, while Mr. H. Lambert was second. Pompons were beautifully shown by several growers, the majority of the plants being well trained, and were furnished by good foliage and flowers. The best six specimens, consisting of Cedo Nulli, Marie Stuart, Mdle. Marthe, Atala, Boh, and Hélène were shown by Mr. C. Holland, Mr. Duffurn being a creditable second. Trained standard plants of any varieties were very superior, notably the specimens of Mrs. Forsyth, Christine, and Guernsey Nugget shown by Mr. Holland, and in this class Mr. Duffurn was again second. Mr. Holland was first for a single specimen of any variety, and most of the exhibitors named took prizes with pyramids of various varieties. Only three groups of Chrysanthemums were arranged, and the exhibitor of the freshest and best of these lost the first prize owing to the neglect to have all the so-called plants rooted—stems with flowers attached being stuck in the pots for the front row. The competition with mixed groups was much more satisfactory, four entering. Mr. W. Brooks was well first for a neat yet effective arrangement in which Ericas, Bouvardias, Solanums, and Orchids were freely used. Mr. Duffurn was a good second, and Mr. E. J. Day, gardener to W. E. Eveston, Esq., third. At the orchestra end of the principal hall there was a grand bank of Ferns and fine-foliaged plants contributed solely by Mr. Brook, who had two first prizes, and Mr. C. Holland, who was second in both instances.

Cut blooms were below the average, only one grower competing in the classes for twenty-four incurved and twenty-four Japanese varieties respectively, and in neither instance was a first prize awarded. This falling off was attributed to the earliness of the Chrysanthemum season, so many of the best blooms being lost. The competition was better in the other classes. With twelve large flowering varieties Mr. Tucker, gardener to Major W. P. Clarke, Trowbridge, was first, and Mr. Holland second, the first-named having the freshest blooms, but which call for no particular comment. Mr. Tucker was also first for twelve Japanese varieties, having fairly good blooms of Boule d'Or, M. J. Pigny, Mons. J. A. Laing, E. Molyneux, Madame C. Audiguier, Sarah Owen, Avalanche, M. Brunet, Madame Baco, Mdle. Laeroix, and Triomphe de la rue des Châlets. Mr. Duffurn was a good second, and Mr. Holland third, a lovely bloom of Grandiflorum in his stand being considered by the Judges the best example of a Japanese variety in the Show. Mr. W. Whitehouse, gardener to R. W. Gibbs, Esq., was first, and Mr. E. Wheeler, gardener to W. Charrington, Esq., second for six Japanese varieties, while the successful exhibitors of Anemone flowered were Mr. Tucker and Col. Mordaunt. Hand bouquets were very lovely, that which gained Mr. Brooks the first prize being only very slightly superior to the second prize bouquet staged by Mr. C. Winstone, Clifton.

Fruit was shown in moderate quantities only. Mr. Duffurn was well first for two good bunches of Alicante, and Mr. W. Hughes second with the same variety. White Grapes were poor. Mr. H. Marshall, gardener to R. Cox, Esq., was first for four varieties of Pears, and Mr. Duffurn second, the other most successful exhibitors of hardy fruit being Messrs. E. Wheeler, J. Thorne, W. Lewis, and T. Tilley.

NORTHAMPTON.—NOVEMBER 13TH AND 14TH.

THE Northampton Chrysanthemum Society scored another success at the Corn Exchange, Northampton, on the above date. Space will not permit us giving the details, but only a few of the leading features of this old established and excellently managed Society. The most striking feature in the Show was the admirable dwarf group from Mr. Underwood, gardener to J. A. S. Bouverie, Esq., Delapre Abbey, Northampton; this was arranged in a space 6 feet by 8 feet, about 6 feet high at the back, which contained fine plants of Madame C. Audiguier, sloping down to about 15 inches in front, that being the height of the plants of L'Adorable from the floor. The other varieties in the front were Triomphe du Nord, Val d'Andorre, Chevalier Damage, Florenee Percy, Avalanche, &c., the blooms being of extremely fine quality, and set on excellent dark green foliage furnished down to the pots. Queen of England, Empress of India, Empress Eugénie, and various other incurved varieties were used, the whole being grown on the cut down system. The specimen plants were arranged around the large hall with very great effect. The trained plants were very well done, although not so large as we sometimes see them, the flowers being elevated evenly above the body of the plant. The first prize collection of Mr. Rollings, gardener to the Rev. A. Longhurst, Abington, contained amongst others a fine plant of Guernsey Nugget. The huge bushes of the untrained specimens made a fine display. The first prize plants from Mr. Gwillam, gardener to Mrs. Shepherd, included a fine specimen of L'Adorable. The amateurs make a great feature at this Show, Mr. Hennings taking the lead with a very creditable group, Mr. G. H. Dunkley, Mr. Seaton, and Mr. W. Dunkley showing well in the other plant classes.

Cut Blooms.—The incurved blooms, like many others we have seen at exhibitions this season, were not quite up to the usual standard, many of them being slightly past their best, showing the season to have been very early this year. For eighteen incurved, distinct, Mr. Dunkley, gardener to Mr. S. Symington, Market Harborough, was first with a very good stand containing excellent blooms of Queen of England, Golden Empress, Princess of Wales, Novelty, Lord Wolsley, John Salter, &c. Mr. F. Perkins, Leamington, was a good second. Mr. Dunkley was also first for twelve incurved; Mr. Kightley, gardener to Sir Hereward Wake,

second. Mr. Dunkley was also to the front in the class for six incurved, distinct; and Mr. Kightley first for six of any one variety. In the principal class of eighteen distinct Japanese Mr. F. Perkins, Leamington, showed fine fresh blooms; second, Mr. Tipler, gardener to Mr. S. Gulliver, Aylesbury, with Mr. H. Dunkley third. In the class for twelve new Japanese introduced since 1885 Mr. Kightley was first, Mr. Tipler second, with Mr. Stevens third. One stand of good blooms contained what the Judges thought to be Comte de Germiny and Golden Dragon under new names, and was disqualified. Some very excellent blooms were shown in the amateurs' division, Mr. Stephens, Great Houghton, taking the lead with Mr. T. Mayes, and Mr. Hennings showing well. Tables decorated with Chrysanthemum blooms formed a very pleasing feature, and Primulas were also shown well. The classes for Grapes were well contested and the collections of vegetables very good, although limited in number. A very fair collection of Apples was sent by Messrs. Smith of Worcester, which was highly commended by the Judges, as was also a fine stand of Japanese and incurved Chrysanthemum blooms shown not for competition by Mr. Fyfe, gardener to Lord Wantage, Overstone, Condor and Avalanche being very fine. To Mr. Draper, the Secretary, and Committee much credit is due for the arrangement of the details of this well managed Society.

GRAVESEND AND MILTON.—NOVEMBER 13TH AND 14TH.

FOR several years this Association has been rather unfortunate in the weather when the exhibitions were taking place, of which this is the sixteenth. 1889 was a favourable exception, but now it has had the disadvantage of being no longer able to have its Show at the commodious Milton Hall. By favour of Mr. Wallis, the Association was able to make its display in two rooms at the Bat and Ball Tavern, Wrotham Road, which were fairly well filled with cut blooms and plants. Of cut blooms a much larger number were sent in than had ever been received before; but in plants there was a notable falling off. As is usual at these Shows there was a large exhibit of fruit and also of vegetables, the staging and other arrangements being skilfully carried out by the Secretary, Mr. Fairey. At 2 P.M. on Wednesday, the newly elected Mayor (J. H. Cooper, Esq.), entered the Exhibition, accompanied by the Mayoress and several members of the Town Council. Having been welcomed by Mr. Kitchingman, in the name of the Association, the Mayor declared the Exhibition open, and in his remarks he commented upon the increased popularity of the Chrysanthemum, and the benefits arising from the development of a love for flowers amongst all classes of the people.

The principal prizewinners were as follows:—Messrs. T. Richardson, gardener to Sir James Fergusson, Singlewell; J. Hollman, gardener to the Rev. W. L. Lewis, Meopham; A. Stevens, gardener to Mr. A. Tolhurst, Northfleet; J. Simon, gardener to Mr. Roberts, Greenhithe; R. Phillips, gardener to Dr. Baber, Meopham; and T. Hosmer, gardener to Dr. Goldenberg, Meopham.

CROYDON.—NOVEMBER 13TH AND 14TH.

THE annual Exhibition of this Society was held in the Skating Rink on the above dates. The exhibits were excellent and the attendance very large. Sir Thomas Edridge, who opened the Show, gave an admirable speech, in which he made special mention of the cottagers' productions and the vegetables from the allotments, which were shown in fine condition. He also spoke highly of the work of the Committee and Secretary, and hoped liberal subscribers would support them and help to make Croydon one of the leading societies.

There were several interesting exhibits staged, not for competition, including a collection of Apples and Pears of sixty dishes from A. H. Smee, Esq., The Grange, Wallington, and a similar exhibit from Messrs. J. Cheal & Sons, Crawley. Messrs. Peed & Sons, Streatham, also sent about forty-five dishes. Messrs. J. Laing & Sons, Forest Hill, filled a recess with a charming group of miscellaneous plants. Mr. T. Butcher decorated the stage of the hall with good taste with plants from his nursery. Mr. G. H. Cooper, florist, Croydon, had nine trained Chrysanthemums all well flowered, and Mr. C. Gibson, Morden Park, had several stands of choice blooms. Classes were provided for groups of fifty Chrysanthemums, but there were only three entries. Mr. G. H. Cooper was the only exhibitor of six trained plants, and he was deservedly awarded first prize.

The prizes in the open class for twenty-four incurved cut blooms, and a corresponding one for Japanese, were strongly contested. In the former, Mr. E. Whittle, gardener to C. H. Goschen, Esq., The Ballards, Addiscombe, was first with good even blooms. Back row: Emily Dale, Jardin des Plantes, Alfred Salter, Golden Empress, Mrs. Cunningham, Queen of England, Lord Aleester, Lord Wolsley. Middle row: Princess Teck, Baron Beust, Jeanne d'Arc, Nil Desperandum, Violet Tomlin, Miss M. A. Haggas, John Salter, Lady Hardinge. Front row: Mrs. Heale, St. Patrick, Prince Alfred, Mrs. W. Shipman, White Venus, Princess Beatrice, Mrs. Norman Davis, and Barbara. Mr. H. Alderman, gardener to G. Hatfield, Esq., Morden Hall, was second with smaller but very compact blooms.

Mr. H. Shoesmith, gardener to M. Hodgson, Esq., Shirley Cottage, Croydon, was first for Japanese with a magnificent stand. The large blooms in the back row were Etoile de Lyon, Avalanche, Madame C. Audiguier, Val d'Andorre, Meg Merrilies, Boule d'Or, Madame Baco, and Condor. Middle row: M. H. Elliott, Sunflower, Jeanne Délaux, Criterion, Mdle. Laeroix, Mr. H. Cannell, Stanstead Surprise, and Mrs. J. Wright. Front row: Thunberg, Thomas Stephenson, Mons. Bernard,

Japonais, Album Fimbriatum, Gloriosum, Triomphe de la rue des Châlets, Mrs. Wheeler. Mr. E. Whittle was a good second. Mr. Alderman was third with a creditable stand. In the local classes Mr. Shoemith secured the chief award for twenty-four incurved, and repeated his success for a like number of Japanese. Mr. C. Ritchings, gardener to W. Lindsay, Esq., Brandries, Beddington, had the best twelve incurved, distinct, staging Empress of India, Golden Empress, Jeanne d'Arc, Hero of Stoke Newington, Lord Alcester, Golden Queen, Queen of England, Alfred Salter, Barbara, Princess of Wales, and Cherub. The same exhibitor was also first for twelve Japanese, and in the class for twelve large flowering varieties with foliage. The best six incurved distinct, and a similar number of one variety, were staged by Mr. Whittle. In the latter Golden Empress was well shown. Boule d'Or was the best from Mr. Shoemith in a class for six Japanese of one variety. Mr. C. Evans, gardener to S. Underhill, Esq., was the most successful with the Anemones, staging good blooms. Fruit and vegetables were a great feature, the latter especially reflecting great credit on the numerous exhibitors.

FAVERSHAM.—NOVEMBER 13TH AND 14TH.

THE third Exhibition of this flourishing Society took place at the Institute Buildings on the above dates, when all available space for exhibits was occupied with plants, cut blooms, fruit, and vegetables, and all the available space for visitors was so full during the whole of the time the Show was open that the officers have every reason to be satisfied with the result of their efforts. The arrangements were in every way carefully carried out, and reflect great credit upon the Hon. Secretary (Mr. C. Stidolph), Mr. L. Jackson, and a band of colleagues too numerous to mention. Every opportunity is taken to make the Show popular. School children are admitted during the dinner hour for 1d., and on Thursday afternoon the inmates of the workhouse were admitted by invitation to a feast of flowers, and through the kindness of Mr. Stidolph they were supplied with something more substantial in the shape of buns and fruit.

The challenge cup for a group of Chrysanthemums brought out six exhibitors. Mr. Cornfoot, gardener to Mr. James Tassell, Faversham, succeeded in securing the premier position, Mr. Louth (the holder) being unsuccessful, the unfavourable mild weather having robbed him of his best blooms. Mr. Redcliff, gardener to Mr. W. E. Rigden, was second; and Mr. Greenslade third. In the open class for twenty-four cut blooms Messrs. Ray & Co. of Green Street staged some grand flowers, which included Stanstead Surprise, Pelican, Emily Dale, and Alfred Salter, and were awarded first prize; the second and third prizes were awarded to Mr. Goodhew, Sittingbourne, and Mr. G. Ray. Incurved blooms were of excellent quality, and for twelve dissimilar Mr. Taylor, gardener to Mr. R. I. Hilton, was first, Mr. Louth second, and Mr. Ratcliff third. For six incurved Mr. Akhurst, gardener to Mrs. Braham, Davington Priory, Faversham, was first; followed by Mr. Weller, gardener to Mr. J. A. Anderson; and Mr. Cornfoot, gardener to Mr. Jas. Tassell, Faversham. In the classes for Japanese the Judges must have had considerable difficulty in selecting the premier positions. For twelve distinct varieties Mr. Taylor was again first, closely followed by Mr. Louth and Mr. Akhurst. For six varieties the successful exhibitors were Mr. Cornfoot, Mr. Weller, and Mr. Rodgers.

The amateurs of this Society take a very conspicuous part, and occupy considerable space at the Exhibition with exhibits of plants, fruit, and flowers, that would, in most instances, do credit to the professional gardener; the premier Japanese bloom of Mr. L. Jackson was perfection. The list of amateur prizewinners is too long to set out, but some of the happy possessors of the principal prizes are Mr. C. Stidolph, the Hon. Sec., Mr. G. W. Wraight, Mr. Dan, Mr. W. T. Jackson, Mr. Goldfinch, and Mr. Burney. There were also a number of classes for cottagers, both for Chrysanthemums and vegetables, all of which were well filled.

The exhibits marked not for competition were a show in themselves. Fine Chrysanthemums were put up by Messrs. Ray & Co. of Green Street. Mr. Fred Hart, of Ospringe Nursery, Faversham, had a grand display of cut blooms, in which there were between fifty and sixty varieties, including many new ones. The attendance at the Show on both days was much in excess of last year, and notwithstanding that many valuable prizes were added to the schedule, the reserve fund will be considerably augmented by the 1889 Exhibition.

BATH.—NOVEMBER 13TH AND 14TH.

THE last of the series of five Shows held annually at Bath was an unqualified success. When comparing the Chrysanthemum Shows in this famous city with those held in other towns it ought always to be remembered that although Chrysanthemums are rightly the leading feature, every encouragement is also given to other plants, as well as fruit and vegetables in season—a really excellent all-round display being the result.

Chrysanthemum Plants.—The competition with trained plants generally is always close and good, no one exhibitor taking a decided lead. This season the premier prize for six large-flowering varieties was awarded to Mr. R. B. Cater, who had perfectly trained well-flowered specimens of Venus, Empress Eugénie, Bronze Jardin des Plantes, Prince Alfred, Mrs. Dixon, and a weak Empress of India. Dr. Budd (Mr. W. Davis, gardener) was a good second, his best being Dr. Sharpe, Mrs. Forsyth, and Lord Wolsley. In the next class, or that for four varieties, and from which the exhibitors in the foregoing were excluded, the first prize was well won by Mr. W. F. Brown (Mr. J. Southard, gardener),

who had very freely flowered specimens of Dr. Sharpe, Mrs. Rundle, Venus, and Empress of India. Mr. G. Lee (Mr. J. Edwards, gardener) was second. The best six specimens of Japanese varieties were shown by the Rev. E. Handley (Mr. S. Kerslake, gardener), who had splendidly flowered plants of Etoile du Midi, Bertier Rendantier, M. J. M. Pigny, Soleil Levant, and Madame de Sevin. Mr. R. B. Cater was second, noteworthy among his being finely flowered plants of Gloriosum and E. Molyneux.

Miscellaneous Plants.—There were a considerable number of well-grown, fine-foliaged, and flowering plants, a judicious use of large specimens of the former adding greatly to the general appearance. There were also several good groups arranged for effect, Messrs. G. Cooling & Sons retaining their old premier position with a bright and pretty bank, in which flowering plants largely predominated. Mr. W. C. Drummond was second, and Mr. T. J. Tate a close third. There was good competition in the class for six Orchids, the Rev. E. Handley taking the lead with plants in excellent condition. Mr. R. B. Cater was a good second, and Mr. J. T. Holmes (Mr. T. G. Horsell, gardener) was third. Bouvardias were poor, and Cyclamen fairly good. The best six table plants out of a strong competition were shown by Mr. C. W. Mackillop (Mr. A. Taylor, gardener), Mr. J. Ayres being second, and Mr. A. R. Baily (Mr. W. Strugnell, gardener) a close third.

Cut Blooms.—Several classes are provided for blooms, and although no tempting prizes are offered the competition was keen throughout. The first prize for twenty-four large flowering varieties was awarded to Lord Heytesbury (Mr. J. Horsefield, gardener), who had very creditable stands, the blooms being arranged as follows:—Back row: Queen of England, Princess of Wales, J. Salter, Empress of India, Golden Queen of India, Mrs. W. Shipman, and Lord Alcester. Middle row: Nonpareil, Cullingfordi, Beauty, Baron Beust, Barbara, Hero of Stoke Newington, Mr. Brunlees, and Mrs. Shipman. Front row: Cherub, Princess of Teck, Golden Eagle, C. Gibson, Venus, Mrs. Heale, Lady Hardinge, and Jeanne d'Arc. Mr. W. M. Baker (Mr. J. Aplin, gardener), Gloucester, was a good second. Lord Radnor (Mr. H. W. Ward, gardener), Longford Castle, was third with smaller but very neat blooms. In the class for twelve large flowered varieties, distinct, the first prize was well won by Mr. A. Cole (W. Carpenter, gardener), Clifton, his best being Queen of England, Bronze Queen of England, Empress of India, and Lord Alcester. Lord Heytesbury was second, and Sir Hussey Vivian (Mr. W. J. Ireland, gardener), Swansea, third. Mr. J. W. Gibson (Mr. J. Ayres, gardener), Clifton, was first for six varieties, Lord Justice Lopes (Mr. W. Robinson, gardener), Westbury, a good second, and Mr. A. R. Baily a close third.

Japanese varieties were well shown. The first prize for twenty-four varieties was awarded to Mr. W. M. Baker, who had fine even blooms. Back row: E. Molyneux, Boule d'Or, Comtesse de Beauregard, George Daniels, Yellow Dragon, W. G. Drover, Carew Underwood, and Mrs. Cannell. Middle row: Album Plenum, Amy Furze, Meg Merrilies, J. Laing, Japonais, Ralph Brocklebank, Avalanche, and Mrs. F. Jameson. Front row: Madame C. Audiguier, M. Boyer, Thunberg, Mr. W. A. Harris, Mr. H. Cannell, Comte de Germiny, Duchess of Albany, and M. Brunet. Sir Hussey Vivian was second, and Lord Radnor was a close third; and was also well first for twelve varieties.

Fruit.—A lengthened report of these classes cannot be given, though they merit more than a brief notice. With a collection of six varieties Mr. H. M. Tugwell (Mr. J. Ellicott, gardener) Bath, was first, having good Lady Downe's and Muscat of Alexandria Grapes, a Melon, Beurré Diel Pears, Cox's Orange Pippin Apples, and Currants. Second, the Duke of Beaufort (W. Nash, gardener), Badminton. Third, E. G. Peacock, Esq. (Mr. W. Fisher, gardener), Bath. The Duke of Beaufort took the lead with four bunches of Grapes in two varieties, having Alicante and Gros Colman in excellent condition. Mr. T. Jones, Coombe Down, was second, and Mr. T. Ravenhill third. Mrs. Gouldsmith (Mr. G. Pym, gardener), Trowbridge, was well first with Gros Colman, and the Duke of Beaufort second, the first named also leading in the any black class with compact, well finished Gros Colman, Mr. E. G. Peacock being second with good Alicante. Mr. G. Read (Mr. J. Chalk, gardener), Salisbury, had a first prize for remarkably well coloured Muscat of Alexandria, Lord Cowley (Mr. J. Gibson, gardener), Draycot Manor, being a good second with the same variety. Pears and Apples were extensively and well shown in the various classes provided for them, some of the principal prizewinners being Messrs. W. Bannister, Westbury-on-Trym; A. Miller, Rood Ashton, Trowbridge; W. J. Smith, E. Hall, E. Fisher, J. E. Ellicott, and W. Nash.

Non-Competitive Exhibits.—The premier position among these must be given to the excellent exhibit of beautifully flowered Cyclamens by Messrs. Sutton & Sons, Reading. From among these the Judges singled out Reading Gem, Giant White, Vulcan, and Butterfly for first class certificates, a certificate of merit being also rightly assigned the whole collection. A certificate of merit was also awarded to Mr. H. Gray, Bath, for a good collection of cut Roses.

TUNBRIDGE WELLS.—NOVEMBER 13TH AND 14TH.

SPLENDID weather favoured the opening day of the Society's Show, which was held in the large and spacious building of the Royal Sussex Assembly Rooms and Corn Exchange on the above dates. Previously the Show was held in the large Drill Hall. The effect this year was certainly marred by being held in two distinct rooms. Trained plants and cut blooms were displayed in one room, whilst groups, fruit and vegetables occupied the other.

Trained plants and groups were the principal features of the Show.

two silver cups being offered in the leading classes. In the first class for a group of eight plants, in pots not to exceed 12 inches in diameter, effect to be the leading feature, Mr. Smooker, gardener to Mrs. Hall, Brathay House, Broadwater Down, easily secured the cup with eight splendidly trained and well-flowered plants of Mrs. G. Rundle, Mr. G. Glenny, Madame C. Audiguier, Chevalier Domage, Prince Alfred, Antonelli, Cullingfordi, and Mrs. Halliburton. Second, Mr. R. Beilby, gardener to W. H. Tindall, Esq., Hollyshaw. Third, Mr. H. Holmwood, gardener to T. Grant, Esq., 3, Hungerford Park. The second class for a group shown in a space 12 feet by 6 feet brought four competitors, Mr. H. Scammell, gardener to C. Reily, Esq., Nevill Park, securing the second cup with an excellent group of dwarf, well-trained plants, carrying fine blooms. M. L. Dupond, gardener to J. Alchin, Esq., Rusthall, and Mr. H. Hemsley, gardener to S. R. Brewerton, Esq., Broadwater Down, were placed equal second.

For six dwarf-trained Mr. J. Smooker was again successful with grand specimens, closely followed by Mr. Beilby. There were two classes for single specimen Japanese, Mr. J. Smooker winning in one of the classes with a good plant of Dr. Sharp; Mr. Tickner, gardener to H. Hewetson, Esq., Broadwater Down, being first in the other class with a grand plant of Val d'Andorre, Messrs. Beilby and Hemsley following. Mr. Beilby was first for four dwarf-trained Pompons, and Mr. Smooker first for a specimen Pompon, Messrs. Beilby and Bachelor following. Mr. Beilby also secured the first place for six pyramids, closely followed by Mr. Tickner.

Cut Blooms.—Numerous classes were provided for these, but the prizes are not of sufficient value to induce exhibitors from a distance to compete. It would be far better for the Society to limit the number of classes, and offer a more substantial prize in the leading class, and thereby secure better competition. In the class for twenty-four incurved blooms, distinct, Mons. L. Dupond secured the first place with small but compact blooms of Cherub, Eve, Guernsey Nugget, Princess of Wales, Baron Beust, Golden Empress, Lord Wolsley, Empress of India—back row. Mrs. G. Rundle, Nil Desperandum, White Venus, Hero of Stoke Newington, Mrs. Heale, Empress Eugénie, Lord Alcester, Mr. Bunn—middle row. Barbara, Isabella Bott, Antonelli, Mr. G. Glenny, Pink Venus, Mrs. Halliburton, Golden George Glenny, and Lady Talford—front row. Second, Mr. E. F. Loof, gardener to G. H. Mason, Esq., Castleton. Mr. W. Avis, gardener to Hon. P. Petre, Faircrouch, Wadhurst, gained first honours for twelve incurved, closely followed by Mr. G. Hickmott, gardener to Mrs. Alnutt, Huntleys. Mr. Avis was also first for six incurved; second, Mr. S. Standen, gardener to E. Beans, Esq., Moatlands, Paddockwood; third, M. L. Dupond.

In the class for twenty-four Japanese the competition was much better. Mr. W. Avis was again first with Thunberg, Carew Underwood, Ralph Brocklebank, Mdle. Lacroix, Edwin Molyneux, Boule d'Or, Lady Lawrence, Comtesse de Beauregarde—back row. Duchess of Albany, Comte de Germiny, Fair Maid, Madame Baco, Mons. Paul Fabre, Val d'Andorre, Gloriosum, Avalanche—middle row. Golden Dragon, Florence Percy, Japonais, L'Adorable, Mrs. J. Wright, Madame Audiguier, Margaret Marrouch, and Mad. Paule Dutour front row. Second, M. L. Dupond. Third, Mr. E. Loof. For twelve Japanese Mr. G. Hickmott came first with good blooms, Mr. J. Standen second, and Mr. E. Loof third. We are compelled to omit reference to the remaining classes, though the fruit is said to have been remarkably fine, and Mr. Charlton contributed effectively to the Exhibition.

GUERNSEY.

THE annual Guernsey Chrysanthemum Show was held in the Market Hall on the 13th and 14th November, under the auspices of the Royal Agricultural and Horticultural Society. The Show was a great success, comprising 3000 cut blooms and stands of splendid plants, the flowers glowing with a brilliancy of colour always to be noticed in this "island of flowers." The chief prizewinners were Mr. Bonammy Dobree, jun., Messrs. Carey, the Misses Mansell, Mr. Carey de Jersey, &c. The size and quality of the blooms could not be surpassed. Lady Dorothy, L'Automne, Chas. Gibson in the incurved section; with Mr. H. Cannell, Mrs. Cannell, Condor, George Daniels, and others among the Japanese were well represented.

The agricultural department of vegetables, roots, cereals, and seeds reflected most creditably on the Guernsey farmers, and by their enormous size and good quality astonished the numerous visitors to the Show. Twelve heads of Mangold Wurtzel weighed 183 lbs., and other kinds were really splendid specimens of produce.

CHISWICK.—NOVEMBER 14TH.

THE annual Exhibition of this Society took place in the Vestry Hall, Chiswick, on 14th inst., and was in all respects a success. Groups of Chrysanthemums were numerous and good. The premier position was taken by Messrs. W. Fromow & Sons, Sutton Court Nurseries, with a capital group of plants. Second, Mr. G. Webb, gardener to J. R. Starling, Esq., The Chestnuts, Gunnersbury. Third, Mr. F. Mears, gardener to J. T. Thornycroft, Esq., Eyot Villa, Chiswick. Extra prize to Mr. C. Padley, gardener to R. L. Cash, Esq., Rupert House, Chiswick. Cut blooms were shown in fine form by Mr. E. Sanderson of "National" fame; Mr. C. J. Waite, Glenhurst Gardens, Esher; Mr. F. Davis, gardener to E. Tautz, Esq., Ealing; Mr. R. Wood, gardener to Mrs. Sanderson, Chiswick; and Mr. E. Chadwick, gardener to E. M. Nelson, Esq., Ealing. A feature was added to the Exhibition by a beautiful display of single and Pompon Chrysanthemums from the Royal Horti-

cultural Society's Gardens. From the same quarter also came some good Grapes and a collection of Apples. Mr. May, gardener to the Marquis of Bute, Chiswick House, sent a beautiful non-competitive group of Chrysanthemums, and a charming miscellaneous group of plants (not for competition) was sent by Mr. Reynolds, gardener to the Messrs. de Rothschild, Gunnersbury Park. The cottagers made a good display both of Chrysanthemums (plants and cut flowers) and vegetables.

PUTNEY.—NOVEMBER 14TH AND 15TH.

THE Putney and Wandsworth annual Show of Chrysanthemums is invariably one of the most attractive in the neighbourhood of the metropolis, although not of large dimensions, and this year's was no exception to the rule. It was held at the Assembly Rooms in the High Street.

Incurved blooms in twenty-four varieties were best shown by Mr. Sullivan, gardener to D. B. Chapman, Esq., Downshire House, Roehampton, and who usually shows very strongly here. He had an admirable stand of flowers, remarkably fresh, of good size, and neatly finished. Among the best were Golden Empress, Hero of Stoke Newington, Violet Tomlin (a fine bloom), John Salter, and Lord Alcester, but several others were well represented. The second prize fell to Mr. Knowles, gardener to Mrs. Egerton, Solna, Putney, who also showed neat bright flowers. The position of these two exhibitors was reversed in the class for twelve. Mr. Knowles' blooms were more even and better finished, the best being an excellent Emily Dale, and good examples of John Salter, Empress of India, Alfred Salter, and Queen of England. In Mr. Sullivan's stand was found the premier incurved bloom in the Exhibition.—a medium-sized example of Golden Empress, with very broad florets. Mr. Bentley, gardener to Sir T. Gabriel, Bart., Edgcombe Hall, Wimbledon Park, was third. The latter won with six, showing well, Mr. Portbury, gardener to W. N. Troy, Esq., Ripon House, Putney Heath, being second.

Japanese were a large and attractive display. In the principal class, twenty-four blooms, Mr. Sullivan was well in advance of his opponents. He had a grand example of Boule d'Or, which was selected as the premier Japanese in the Exhibition, also good blooms of Gloriosum, Mdle. Lacroix, Etoile de Lyon, Lady T. Lawrence, Madame Baco, and Baronne de Prailly. Mr. Knowles followed with much smaller flowers. Mr. Hendon, gardener to D. B. Beresford, Esq., Castletower, Wimbledon Common, was third. There were several stands of twelve, a capital collection from Mr. Sullivan being placed at the head of the list; Baronne de Prailly, Boule d'Or, Etoile de Lyon, and Gloriosum were finely shown, and the others, though small, were extremely fresh. Medium sized, well-coloured blooms from Mr. Knowles were placed second, and Mr. Newell, gardener to Sir E. Saunders, Fairlawn, Wimbledon Common, received the remaining award. The latter did better with sixes, winning by a few points from Mr. J. Carter, gardener to Miss Parry, Heathside, Wimbledon Common, and Mr. J. Bentley. In other classes for Japanese and incurved Messrs. Dark, gardener to J. Hooker, Esq., Lomond House, Richmond Road, Putney; W. Page, gardener to H. Chester, Esq., Royston, Putney Hill; F. Munt, gardener to T. Norton, Esq., Dryburgh House, Putney; Bartley, gardener to Miss Tuppin, Upper Richmond Road, Putney; and E. Moe, Feldheim, Wimbledon Common, secured prizes. Dr. George Walker, 12, Lingfield Road, Wimbledon, showed best amongst the amateurs.

Reflexed were not very extensively exhibited, but Mr. Knowles won easily, Mr. Hendon being second. Mr. Bentley won with Pompons, a fresh neat stand, Messrs. Grounsell, gardener to J. Langton, Esq., Millbrook, Putney, and A. Methven, gardener to W. Keiller, Esq., Fernwood, Wimbledon Common, following. Mr. Sullivan had the best Anemone flowered, a very fine stand.

The groups were good and formed a capital feature. Mr. Springthorpe, gardener to R. Alexander, Esq., Gifford House, Roehampton, was the winner with a fine group, which was composed of healthy plants bearing fine blooms. Excellent, too, was the second prize group of Mr. Carter. Mr. Barter, gardener to A. Venables, Esq., Hollywood, Wimbledon Park, and Mr. Townsend, Providence Nursery, Putney, were third and fourth.

Specimen plants were finely shown by Mr. Bentley, who was first in nearly every class, Messrs. Grounsell, Knowles, and Lacey, Upper Richmond Road, Putney, securing the minor prizes. Amongst the amateurs J. Pepper, Esq., Eaton Lodge, St. John's Road, Putney; Miss Toppin, H. Richardson, Esq., Springfield Lodge, Upper Richmond Road, Putney; W. E. Oates, Esq., 263, Upper Richmond Road, Putney; and H. Trengrouse Esq., Danehurst, Upper Richmond Road, were accountable for most of the prizes. Wreaths of Chrysanthemums and Maidenhair were very beautiful, Mr. Portbury having the best.

Fruit and vegetables were excellent, but space cannot be found for details of the classes. Mr. Griffin, gardener to Miss Christy, Coombe Bank, Kingston-on-Thames, deserves mention, however, for some splendid Grapes. Stove, greenhouse, and table plants also added an attractive feature to the display.

TEDDINGTON.—NOVEMBER 14TH AND 15TH.

A BRIGHT and pretty Exhibition was provided in the Town Hall, Teddington, last week, and though the extremely unfavourable season had necessarily reduced the number of entries to some extent, yet there were amply sufficient to make a show thoroughly creditable to the district and satisfactory to the Committee. A comprehensive schedule was carefully prepared, prizes being offered for cut blooms, specimen

plants, groups, floral decorations, miscellaneous plants, fruit and vegetables, the spacious hall being well and effectively occupied. The Society has been in existence seven years and has done good work in the neighbourhood, an enthusiastic amateur horticulturist, the Treasurer, Mr. W. Furze, having been mainly instrumental in promoting its success, in which he has been assisted by Mr. Douët, Mr. Howard, and other members of the Committee. Substantial local support has been secured, in consequence of which, together with the receipts at the doors, the Society is in a satisfactory financial condition. A great attraction is afforded by the amateur musical entertainments arranged by Mrs. Furze, and this year they proved extremely good.

Cut blooms were fresher and more numerous than might have been expected in such a season as this, and in some of the classes the competition was extremely close. The chief interest centred in that for twenty-four blooms, twelve incurved and twelve Japanese, distinct, the first prize consisting of a handsome challenge cup and a money prize, the cup to be won twice, not necessarily consecutively. The first cup was finally won by Mr. W. Furze (gardener, Mr. E. Coombs). The present cup had been won twice by different exhibitors, and this year Lieut.-General Vials, C.B., Teddington (gardener, Mr. T. Higginson) succeeded in winning it for the second time, and it thus became his property. The blooms were fresh, bright, of good substance, being arranged as follows:—Incurved, back row: Queen of England, Golden Empress, Empress of India, and Lord Alcester. Middle row: Lord Wolseley, Princess of Wales, Prince Alfred, and Mrs. Heale. Front row: Jardin des Plantes, J. Salter, Lady Hardinge, and Mr. Brunlees. The Japanese were, in the back row: Avalanche, Boule d'Or, Madame J. Laing, and Ralph Brocklebank. Middle row: Madame C. Audiguier, Meg Merrilies, E. Molyneux, and Fair Maid of Guernsey. Front row: Marguerite Marrouch, Golden Dragon, Maiden's Blush, and Duchess of Albany. The second prize was secured by Mrs. Holberton, who had good even blooms, both of incurved and Japanese. Another capital class was that for twenty-four incurved, in which Mr. W. Furze took the lead with excellent blooms, arranged in this order:—Back row: Lord Alcester, Alfred Salter, Empress of India, Lord Wolseley, Empress of India, Prince Alfred, Jeanne d'Arc, and Emily Dale. Middle row: John Salter, Miss M. A. Haggas, Violet Tomlin Mrs. Heale, Mr. Brunlees, Princess of Wales, Lady Carey, and Mr. Bunn. Front row: Princess Teek, Mrs. Shipman, Baron Beust Mabel Ward, Princess Beatrice, Barbara, Perle Précieuse, and Lady Hardinge. The same exhibitor was also first with twenty-four Japanese, fine handsome blooms, representing the following varieties:—Back row: E. Molyneux, Etoile de Lyon, Madame C. Audiguier, Boule d'Or, Stanstead White, Japonais, Ralph Brocklebank, and Avalanche. Middle row: Belle Paule, Marsa, Sunflower, Mrs. J. Wright, Duchess of Albany, Comtesse de Beauregarde, Condor, and M. Elliott. Front row: Mrs. F. Jameson, Hogarth, Val d'Andorre, Yokohama Beauty, Mrs. H. Harris, Gloriosum, Hamlet, and G. Daniels. In other classes, notably with twelve incurved, twelve Japanese, twelve Anemones, six Japanese of one variety, six Japanese Anemones, and twelve large Anemones, Mr. Furze gained premier prizes. Two series of classes were provided, one being open to all members of the Society, the other restricted to the immediate neighbourhood. A few also were appropriated to amateurs who do not employ assistance in the garden more than three days a week. In all of these the exhibits were good, some of the chief exhibitors being C. Fletcher, Esq., The Shrublands; Mrs. Cowan, Park Lodge; W. Millwood, Esq., The Woodlands; Lieut.-Gen. Viall; T. P. Chappell, Esq., Weir Bank (gardener, Mr. Davies), who had capital blooms in several classes; E. H. Douët, Esq.; and Dr. Walker; with Messrs. W. Bates, Lambert, Piper, Clarke, Cave, Higginson, and Gregory. Groups and specimen plants were not very numerous, but of good quality.

An interesting and attractive portion of the Show was that devoted to floral decorations, chiefly stands of Chrysanthemums and buttonholes, and considerable taste was displayed in the arrangement of the competing contributions. The buttonholes were exceedingly good, and the six with which Miss Furze won the first prize we have never seen surpassed in the material employed and the tastefulness of the arrangement. A few flowers of Orchids were used with Neapolitan Violets, Adiantum gracillimum, and Asparagus plumosus, but they were combined with an artistic grace too rarely seen in such productions. Miss Howard, The Grove, Teddington, was an admirable second, Orchid flowers being similarly used with excellent effect; these two exhibits constituting studies from which the most experienced floral decorators might have learned something. Mrs. R. Gardiner was third with neat and pretty buttonholes. Miss Howard was accorded premier honours for an elegant silver stand, in which bronzy red and yellow Japanese Chrysanthemums, with Adiantum cuneatum fronds, were used with excellent effect, Miss C. Wragg following with an arrangement of pink and white Chrysanthemums, Asparagus plumosus, and other foliage. Two stands of autumn flowers, fruit, and foliage gained for Miss Montgomery and Miss Wragge equal first prizes for two very distinct styles, but equally meritorious—one notable for the lightness of the material and arrangement, the other, though a little heavier, displaying a charming combination of light and yellow Roses, dark foliage, with Crataegus fruits and Strawberries.

Fruit was well represented, Apples and Pears especially. Mr. Davies won the first prize for three dishes of fruit, excellent Grapes, Apples, and Pears, Mr. Bates following closely. Vegetables also were capitally displayed, the exhibits in the cottagers' classes numerous and good.

LEICESTER.—NOVEMBER 15TH.

THE Leicester and Midland Chrysanthemum Society took a distinct step in advance this year in providing open classes with substantial prizes, the first for forty-eight blooms in thirty-six varieties, half incurved and half Japanese, being £10. The Exhibition was held in the Temperance Hall, a capacious and handsome building with organ and orchestra, and was in every way a gratifying success. The Show was opened by the Mayor, and on the evening of the first day a high-class vocal and instrumental concert was held in the Hall, several accomplished performers appearing gratuitously on the occasion. A band of children, boys and girls, highly trained by Mr. J. Muston, was a delightful feature in the proceedings. But we must turn to the flowers. Prizes were not offered for plants, indeed there was no room for specimens, and the central portion of the Hall was sufficiently furnished by two bright groups of Chrysanthemums, Messrs. J. & H. Hickling, Loughborough, and Mr. Henry Jordan, Ayleston Park, receiving the prizes in the order named. It was essentially a show of cut blooms, and an excellent one, smoothness and general good quality prevailing throughout the classes, not excluding those devoted to amateurs, which were of a highly creditable character.

In the chief class of forty-eight blooms seven excellent collections were staged, the first position being won by Mr. J. Lambert, gardener to Colonel Wingfield, Onslow Hall, Shrewsbury. His incurved flowers were not of the largest size, but smooth, firm, and of high quality. His back row contained Lord Alcester (2), Alfred Salter, a deep buff sport from Lord Alcester, Golden Empress (2), and Queen of England. Middle row: Princess of Wales, Jardin des Plantes, Princess of Teek, Mrs. Shipman, Jeanne d'Arc, Violet Tomlin, Lord Alcester (sport), and John Salter. Front row: Mr. Brunlees, Eve, Barbara, Lord Eversley, Mrs. N. Davis, Refulgens, Mabel Ward, and Miss M. A. Haggas. Japanese—Back row: Stanstead White, Thunberg, Madame C. Audiguier, Comte de Germigny, Madame J. Pigny, Boule d'Or, Baronne de Prailly, and Etoile de Lyon. Second row: Sarah Owen, W. G. Drover, J. Délaux, Meg Merrilies, Madame Laing, Carcw Underwood, Ralph Brocklebank, and Avalanche. Front row: Mons. Bernard (2), Condor, Sunflower, Belle Paule, E. Molyneux, Criterion, Madame Baco—a heavy fresh, fine lot of blooms. Mr. John Dilley, gardener to W. H. Hay, Esq., Great Bowdon Hall, won the second place. His Japanese were splendid, full, fresh, and even. The incurved were of medium size, several of them good, all well formed, but a few a little stale. Third honours fell to Mr. P. Blair, Trentham Gardens. Some of the incurved blooms were of large size, and his stand surpassed the corresponding one of Mr. Dilley, but the Trentham Japanese fell off considerably, notwithstanding a few splendid blooms in the stand. In the open class for twelve incurved blooms, distinct, Mr. Lambert won the foremost place, Mr. W. Bolton being second; the positions of these exhibitors being reversed in the Japanese class, both staging high-class blooms.

In the amateurs' class for twelve incurved blooms, Mr. F. H. Anthony, Leicester, won the chief position with very neat and good blooms of Hero of Stoke Newington, Empress of India, Miss M. A. Haggas, Jeanne d'Arc, Jardin des Plantes, Mr. C. Gibson (good), Lord Hardinge, Barbara, Baron Beust, Violet Tomlin, Mr. Brunlees, and Princess of Wales. Second, Mr. John Read, Ayleston Park; third, Mr. Charles Day. Mr. John Waite, Leicester, was first in the class for six blooms, winning the N.C.S. medal with an excellent stand of Lord Alcester, Alfred Salter, Jeanne d'Arc, Queen of England, Golden Empress, and Empress of India. Second, Mr. John Read, with extremely neat blooms; third, Mr. F. H. Anthony.

Bouquets were numerous and good, as also were baskets of Chrysanthemums and Ferns—an excellent class. Mr. Perkins, Coventry, was first with a bouquet; and Mr. Perkins, Leamington, with a basket.

Messrs. Richard Smith & Co., Worcester, exhibited a splendid collection of Apples, and Mr. Lambert secured the chief prizes for black and white Grapes.

The orchestra was attractively furnished by Mr. James Wright nurseryman, and the Show was well arranged by Mr. John Read, the Honorary Secretary, Mr. W. K. Woodcock, and other assistants.

An excellent luncheon was provided for the Committee, Judges, and friends, by Mr. A. Angus at the "Carlton," a high-class commercial hotel, of which the once Chiswick student and fruit foreman is the popular and successful proprietor. In the evening a crowded meeting of Chrysanthemum growers was held in one of the rooms of the Temperance Hall, Mr. J. Wright presiding. Mr. Woodcock read a paper on Chrysanthemums—historical and practical—an interesting discussion, ensuing, which may possibly be further alluded to when the great pressure on space is relieved.

CHESHUNT.—NOVEMBER 15TH AND 16TH.

COMPARATIVELY few Shows are held on Fridays during the Chrysanthemum period, but that was the day selected for the Cheshunt Exhibition, to which St. Mary's Hall was devoted, and notwithstanding the early season, the date did not prove so unfavourable as might have been expected. The entries were fairly numerous, and the quality of the blooms so nearly equal that in several cases their positions could only be determined by close and careful pointing. It was altogether an extremely satisfactory display, and Mr. R. Ewing, who really projected the Society six years since, and who has supported it most energetically ever since, deserves great credit for the result of his efforts. Dr. Evans and Mr. George Paul also take considerable interest in the Society, and have assisted greatly in furthering its advance.

Cut blooms constituted the chief feature of the Exhibition, and the

leading class was that for twenty-four blooms, twelve incurved and twelve Japanese, not more than two blooms of one variety. There were three entries, but the contest for the first prize was really confined to two of these, which were nearly equal in merit, the incurved in the one almost balancing the Japanese in the other. Ultimately, after most carefully estimating the merits of the individual blooms, the premier award was secured by R. Ewing, Esq. (gardener, Mr. Bettesworth), by three points. The Japanese were extremely handsome blooms of rich colours, comprising the following—Back row: Sunflower, Avalanche, Mrs. Wheeler, and Ralph Brocklebank; middle row: Mrs. Wheeler, Ralph Brocklebank, Mdle. Paule Dutour, and Sunflower; front row: Madame Baco, Mdle. Paule Dutour, Japonais, and Madame Baco. The incurved were not quite so large or substantial, but they were fresh—Back row: Golden Empress of India, Emily Dale, Queen of England, and Miss M. A. Haggas (very fine); middle row: Emily Dale, Mrs. Heale, Miss M. A. Haggas, and Empress of India; front row: Princess of Wales (2), and Mr. Brunlees (2), all four weak. Mr. Collins, Ponsbourne Park Gardens, was second with extremely fine incurved blooms, but rather weaker in the Japanese. With twelve Japanese and twelve incurved, however, the last named exhibitor secured the premier award, being followed by Messrs. C. Cox and J. Turk. For six Japanese Messrs. J. Gilbert and J. Turk won the prizes in the order named, and with large Anemones Mr. Gilbert also took the lead, and was followed by Mr. Collins, both showing extremely well. In several other classes for cut blooms the exhibits were also good.

For a group of Chrysanthemums Mr. Collins won the first prize, having dwarf plants bearing good blooms well arranged. Mr. G. T. Howard was second with tall plants, but effectively arranged. The best miscellaneous group was shown by Mr. J. Walter, gardener to S. Warren, Esq., Dendrobiums, Cypripediums, Poinsettias, Palms, and Ferns tastefully disposed, Mr. Bryant following with a bright but too crowded group, in which the colours were not well harmonised. Mr. Ewing had first prize for a group of Pompons in 60-size pots, the plants 6 to 12 inches high, and well flowered. They were very ornamental and useful little plants, being grown on from cuttings inserted three in each pot in early summer. The same exhibitor showed a non-competing collection of thirty-six Japanese blooms (highly commended), including handsome examples of Ralph Brocklebank, Meg Merrilies, Sarah Owen, Japonais, and Boule d'Or. Messrs. Bryant and Turk exhibited well grown plants of Chinese Primulas, taking the first and second prizes respectively. Messrs. G. Paul & Son, The Old Nurseries, Cheshunt, also contributed some handsome Primulas of the best strains, and a large graceful group of Bamboos.

WATERFORD.

THE Show here on Saturday was not large, except in fruit, vegetables, and farm produce; but in regard to Chrysanthemum cut blooms the exhibits were remarkably fine and staged in splendid condition. Two of our most successful exhibition growers entered the lists, and possibly had the effect of scaring away less noted growers. The schedule was not pretentious, and the first class (not noting specimens or plants in pots, which left plenty of room for improvement) was for twelve incurved, six distinct varieties; and first place went to Mr. John Crehan, head gardener to Mrs. Malcomson, Minella, Clonmel, who had immense blooms of Blush Queen, Golden Queen, Jeanne d'Arc, Lord Alcester, Empress of India, Alfred Salter, Golden Queen, Lord Wolseley, and Prince of Wales. The second prize, with nearly the same varieties, went deservedly, by merely a few points, to Raymond De La Poer, Esq., Kilkronagh, Waterford (head gardener, Mr. Crawford), who had remarkably fresh and neat, though something smaller blooms. With twelve Japanese, not less than six varieties, Mr. Crehan won by two points with Thunberg, Edwin Molyneux, Bronze Dragon, Avalanche, Criterion, Boule d'Or, and Dormillion staged in this order. Mr. Crawford was second. The Hon. Dudley Fortescue showed well in this class (gardener, Mr. J. A. Calthorpe). We understand Mr. De La Poer would have done better only his best flowers went to Dublin the previous day, where he had first prizes in all the classes he entered for. Japanese, reflexed, and Anemones.—Here he had first prize for reflexed, which were admirable; but having two splendid blooms of Amy Furze the Judges, going by the National Society's catalogue, considered these inadmissible in a reflexed class. The varieties were Cloth of Gold, Cullingfordi, Amy Furze, Christine, Cloth of Gold, Chevalier Domage, Pink Christine, White Christine, and Golden Christine. First prize for amateurs also went to Kileronagh, the following being well shown:—Fabian de Médiana, Lady Margaret, Madame Cabrol, Nelson (fine, new), Lady Margaret, Empress, Sabine (new), Fleur de Marie, J. Thorpe, junior (new), George Sand, and Grande Alvéole. C. Percival Botton, Esq., who was assisted by J. A. Power, Esq., was a most efficient and courteous Secretary, while the Judges were Mr. P. Atherne, head gardener to the Duke of Devonshire, Lismore Castle, and your correspondent—W. J. MURPHY, Clonmel.

TWICKENHAM.—NOVEMBER 19TH AND 20TH.

CONTRARY to all expectations this Show, notwithstanding the lateness of the date for the south, proved an excellent one—indeed, in some respects it was the best the Society has yet held. The Town Hall, devoted to the Show, was crowded with exhibits, both in the main hall and the galleries, bright colours effectively arranged and highly satisfactory quality in the majority of the classes being the distinguishing features. Much credit is due to the Hon. Secretary, Mr. J. J. Pugh, whose courteous manner secures many friends; and to Mr. W. Bates, whose practical experience is invaluable.

The groups of Chrysanthemums constituted a capital display, Mr. Parsons, gardener to T. Twining, Esq., winning first honours with an admirable arrangement, well finished off in front with healthy Maiden-hair Ferns. The Chrysanthemum blooms were large, the colours well proportioned, and the plants of moderate height. Mr. Rickwood, gardener to Lady Freake, was a close second, with fine quality blooms and well arranged colours, the plants a little tall in the front. Mr. J. Waldie, gardener to J. Bigwood, Esq., was third, also for very well grown plants, with fine blooms but rather tall. Mr. Brittain, gardener to W. Brigg, Esq., was fourth. Specimen plants were shown by Messrs. Salloos and Cave, who were first and second, the former with dwarf trained plants, the latter with pyramids.

Cut blooms were far better, both in numbers and quality, than might have been expected, though, of course, they showed some effects of the season. For twenty-four blooms, twelve Japanese and twelve incurved, W. Furze, Esq., Teddington (gardener, Mr. E. Coombs) was first with excellent even blooms, followed by Mr. Waite and Mr. Higginson, amongst five exhibitors. For twelve incurved, Mr. Furze was also the premier exhibitor, staging compact neat blooms, Mr. Higginson and E. H. Donët, Esq., being second and third. Mr. Furze continued his success by taking first prize for twelve Japanese, Messrs. Futeher and Higginson following, all showing well. For twelve Pompons Mr. Furze led with beautiful blooms, Mr. Donët following with good examples rather smaller. Mr. Furze also had the best twelve large Anemones, and the best six incurved of one variety (Barbara). Mr. C. Garrod won premier honours for six Japanese of one variety with Thunberg, very fresh and good, Mr. Futeher following with Ralph Brocklebank of excellent colour.

A beautiful feature was formed by the vases of flowers in competition. Miss Clarke was first with a most graceful stand, in which Marguerites, Pancratiums, white Azaleas, and Grasses were used with charming effect. Miss Müller was second with a small, neat, and unpretentious stand; Mrs. R. M. Gardner being third with a tall, graceful stand not quite finished in the centre. For a stand of autumn leaves, berries, and flowers, Miss Prior was first for an effective arrangement of Marguerites, Roses, and Grasses. Mr. Newman of Bromley had the best bouquet, an exceedingly tasteful production; and Miss Clarke the best basket of Chrysanthemums. Table plants were well represented by Messrs. C. Coombs, Waite, and Parsons, who took the prizes in that order in a strong class.

In the class for a collection of four dishes of fruit Mr. Davies, Weir Bank Gardens, Teddington, was a good first, showing an excellent Pine, good black Grapes, Beurré Diel Pears, and King of the Pippins Apples. Mr. T. Buckland was second and Mr. Wadham third. With Pears Messrs. Garrod, Waite, and Fitzwater were the prizewinners. For Apples Messrs. Waite, Garrod, and Rickwood secured the prizes in a good competition. Mr. Waite had the best black Grapes (Alicante), followed by Messrs. Rickwood and Woods, Mr. Mitchell having the finest white Grapes (Mu-cat of Alexandria). With vegetables Mr. C. J. Waite took the lead, closely followed by Messrs. Higginson and Garrod.

Amongst the non-competing exhibits the group of Orchids from H. Little, Esq., was most praiseworthy, Cypripedium Spicerianum being grandly shown. An excellent group of Orchids was also staged by Mr. W. Gordon, groups of Richardias and Chrysanthemums by Messrs. Hawkins & Bennett, a tasteful group by Mr. H. E. Fordham, fine collections of Cyclamens by Messrs. W. D. Clarke and J. Walker, grand Celery, Seakale, and Apples from Mr. Poupart, Gourds from Messrs. Wallace & Co., and fine Chrysanthemum blooms from Mr. W. Bates, Poulett Lodge Gardens.

HARDY FRUIT GARDEN.

LIFTING FRUIT TREES.—To be successful with cordon, bush, or other miniature trees they must be well attended to at the roots, otherwise the chances are there will be much wood growth formed, and but little fruit produced. Lifting the roots and improving the soil is also the best remedy for the other extreme—viz., abundance of bloom, followed it may be by comparatively worthless fruit, little or no wood growth being formed. What is wanted in all cases, or whether the trees are on free-growing or dwarfing stocks, is abundance of root fibres near the surface. Lifting, if properly done, is one of the best means of correcting downward root action, good surface culture, including mulchings of manure, or, better still, half-decayed leaves and manure from old hotbeds, will do the rest. If annual or biennial liftings, partial or complete, cannot be resorted to, the least that can be done in the case of all young trees is to lift and lightly root-prune during the second or third winter after planting. This may give a temporary check to the top growth, and which, in the case of wall trees with plenty of head room, may be thought undesirable, but it will most probably

obviate the necessity for more drastic measures later on. It is a case of prevention of deep root action, abundance of surface root fibres maintaining the trees in a productive state, whereas when they are furnished with deep running fibreless roots only, much wood growth and fitful crops of inferior fruit are the sure consequence.

THE PROCESS DESCRIBED.—In all cases where trees must be kept in a rather small compass, severe pruning being resorted to if necessary, it pays to lift the trees every season. This being an annual process, a thicket of roots are formed, and not the slightest ill effects to the crops result from the lifting, nor is it a great undertaking. A fairly wide, deep trench should be opened at about 4 feet from the stem of the trees, and from this the roots can be undermined, all but the deep running roots being preserved, and again relaid in a mixture of old soil and either fresh loam or half-decayed leaf soil. The fresh compost is taken possession of during the next growing season, and fruit of the best quality, frosts permitting, results. Pyramids do not receive the full benefit of the sunshine all round, and for this reason it is advisable to half-turn them round each time they are lifted, by which means they are maintained in a generally well-ripened productive state. Pyramid and espalier-trained Pears on the free-growing or Pear stock, and which it is desirable should increase considerably in size, must not be so severely handled, but if carefully undermined so as to cut through or bring up the deep running roots every third year, and the roots exposed relaid in fresh compost, the top growth would be both sturdy and fruitful, the quality of the fruit being greatly improved by this treatment. Apples, Cherries, and Plums pay for similar treatment at the roots, the longevity of the trees, as well as their productiveness, being fostered by good root culture.

APRICOTS.—There are numerous gardens in this country where Apricots cannot possibly be profitably grown, the reason for this being hard to determine, though probably one of the principal causes of failure is to be found in the nature of the subsoil. The complete removal of a cold clayey subsoil, and the substitution of good turfy loam, or this, the ordinary surface soil, leaf soil and charred rubbish in mixture will be attended with good results, though even this is of little avail if the site is not fairly warm, high, and dry. In many instances it is no easy matter to collect sufficient fresh compost to take the place of the subsoil, but the only alternative is to plant rather high or well above the ordinary garden level, root lifting being resorted to every autumn. In some districts, notably where at times the water cannot get away freely, and unfortunately there are numerous gardens thus badly located near streams, it is found necessary to ward off all late autumn and winter rains from the Apricot borders with the aid of shutters, more than sufficient moisture ascending from below.

PEACHES AND NECTARINES.—These, notably Peaches, might more often be successfully grown if more attention was paid to the roots. When originally planted in a wide rich border they grow much too strongly at the outset, the wood failing to ripen properly, and un-ripened wood in addition to being unfruitful is not of a suitable character to lay the foundation of serviceable trees. If a new site is selected for them use comparatively poor, yet fresh, loamy soil, taking care beforehand to well and deeply drain the border. In most instances, however, it is old sites that are prepared, and seeing that the soil must be exhausted, much of this should be taken away, and fresh turfy loam or the compost recommended for Apricots substituted. If the trees are planted firmly in this, care being taken to keep rather above the garden level and also not to bury the roots deeply, a good start will be made. Completely relifting may even then be necessary after the second or third season's growth in order to check grossness, and this operation ought to be repeated not less often than every second autumn, though some successful growers make it annual practice to lift all their Peach and Nectarine trees. The roots must be kept out of the subsoil, or the top growth will in most instances be unsatisfactory. Hundreds of both young and old trees that have never been lifted since they were planted in various parts of the country would be greatly improved in health and productiveness if lifted, and otherwise taken in hand at once. After all it is not such a very serious undertaking this undermining either large or small trees, while the results are usually extremely gratifying. The roots should be carefully searched out, lightly shortened and relaid in fresh compost much nearer the surface than heretofore.

FRUIT FORCING.

VINES.—*Houses Cleared of Grapes.*—Directly the Vines are leafless and the Grapes cut attend to the pruning. If the Vines are strong, having stout, short-jointed wood, they may safely be pruned to a couple of eyes. If, however, the base buds are small, and the Vines have not from similar buds in previous years given as large bunches as desired, the laterals may be left a little longer. It is necessary that a plump round (not flat) well developed bud on stout, hard, thoroughly ripened wood be selected for pruning to, striving for a close compact bunch of well-set berries with a stout footstalk in preference to a large uneven bunch, which usually follows large flat buds on long-jointed wood, the foliage supporting such being large, thin, and incapable of elaborating the food and concentrating it in the buds at their base. Avoid pointed buds, they are usually not productive of bunches, and if they are on long-jointed wood the bunches have a tendency to revert into tendrils. Wash the house thoroughly, and cleanse the glass. Remove only the loose bark; avoid the customary scraping. Tepid soapy water is unquestionably the best means of cleansing the Vines, using a brush with care and judgment, following with an approved insecticide. Remove the mulching or loose surface material down to the roots, and place on a

couple or 3 inches thickness of fresh loam, mixed with some old mortar rubbish passed through a three-quarter inch sieve, night soil, soot, and wood ashes. If the loam be light add some clay marl dried and reduced to powder. Of turfy loam cut 3 inches thick and chopped moderately small have twenty bushels, of sifted old mortar rubbish add two bushels, of night soil mixed with an equal proportion of dry earth one bushel, soot half a bushel, clay marl (if the loam be light) two bushels, and one bushel of steamed bone meal. Charcoal dust may be added to the extent of four bushels, together forming a compost, when thoroughly incorporated, good as a dressing for Vine borders, alike as a rooting and feeding area. The early watering will wash the assimilated matter down to the roots, and fresh feeders encouraged into it can be kept there by surface dressing or mulching with short manure after the Grapes are set, feeding with liquid manure as necessary. If the houses must be used for plants they should be kept cool, admitting air freely, not exceeding 40° to 45° by artificial means. It is best, however, to dispense with the plants, admitting air in all but severe weather, a few degrees of frost doing no harm to the Vines, but ensuring more complete rest.

Houses of Thin-skinned Grapes.—Although the somewhat heavy and continued falls of rain have saturated the soil and atmosphere yet Black Hamburgh Grapes have kept well, though in a saturated border it is liable to damp at the footstalks, and the berries to fall, particularly when the Grapes have been ripe for some considerable time. Madresfield Court keeps better than Black Hamburgh, not being so liable to suffer from damp, and the liability to crack is at an end as soon as the wood and foliage are thoroughly ripened. Indeed Madresfield Court keeps capably until the end of November, and equal to any thin-skinned variety until January. Black Hamburghs have kept colour better than usual, those ripened early in August being still good in colour, and particularly rich and sugary. The foliage is nearly all down, and after this is effected Hamburghs lose colour, and in a dry atmosphere shrivel rapidly. Similar remarks apply to Foster's Seedling and all the thin-skinned varieties. Vines, however, of these varieties that ripen their crops in September have the foliage still fresh, and will bear more moisture at the roots and in the atmosphere than those that have had the Grapes ripe since August. Indeed a moderate amount of air moisture is necessary to prevent undue evaporation and the shrinking of the Grapes, it not being so much air moisture as a stagnant atmosphere that is fatal to the keeping of Grapes. Slight warmth in the pipes will be required constantly to maintain an equable temperature, but this must not be high or it will cause the berries to shrivel prematurely, 50° not being exceeded by artificial means, ventilating freely and early in bright weather, so as to prevent moisture being condensed on the berries. The outside borders have been protected from rains by shutters or other material, and if inside borders too are covered with straw the Grapes will keep better. Covering the border prevents it cracking, and keeps down moisture likely to arise and prove injurious.

Earliest Forced Vines in Pots.—The earliest started will now be showing signs of growth, so that the temperature may be slightly increased—55° minimum and 66° maximum by fire heat, with 10° more from sun heat, proportionately increasing the atmospheric moisture. The ventilation will require to be moderate, and what is given should be at the top of the house. If side ventilation be employed the cold air must be made to pass the heating surface so as to become warmed, for cold currents of air are extremely pernicious.

CUCUMBERS.—Cold weather is very trying, as the continuous firing dries the atmosphere more than is good for the foliage, the fruits becoming stunted and swelling indifferently, and when the pipes are close to the roots the soil is dried too much for healthy growth. Be careful in ventilating, providing it, however, whenever a favourable opportunity offers, but not when the external air is sharp and cold. In bright but cold weather turn off the top heat when the sun is powerful and likely to raise the temperature above 80° in such weather, damping the house morning and afternoon, closing early. Care must be taken in damping so as not to wet the embryo fruits, or they will damp off. Water will be required at the roots about twice a week. A temperature of 60° to 65° at night, and 70° to 75° by day is suitable.

The early winter fruiters or plants from the August sowing, and planted out in September, have grown to the extent of the trellis or nearly so. Unless there is undue vigour in the plants they should not be allowed to fruit for a few weeks. Attend frequently to stopping, thinning, and tying the shoots, avoiding overcrowding and overcropping as the two greatest evils, subduing canker at the collar with quicklime well rubbed into the parts affected, removing every decayed leaf promptly. If mildew appear dust with flowers of sulphur, it being well to distribute some over the plants before mildew is seen. Aphides should be destroyed by careful and moderate fumigation with tobacco.

PLANT HOUSES.

Lapagerias.—Where these are grown in a little warmer house than an ordinary greenhouse they will have practically ceased flowering, and may be taken carefully from the roof to permit washing the glass and woodwork thoroughly. Some care is needed in taking the plants down, as their foliage is brittle, and the leaves are very easily broken from the stem. If aphides or thrips have established themselves on the plant dip them in a solution of tobacco water placed in a tub or tank. These insects are easily eradicated while the plants are loose. Thrips quickly destroy the foliage, and must be exterminated directly they are observed. Brown scale will also infest these plants, and while they are down it is wise to remove all by the sponge from the foliage. When

the plants are secured to the trellis again they should be syringed with petroleum and water; they will bear without injury 3 ozs. to four gallons of water. This is the best solution for scale, and will also destroy thrips at the same time. During the operation of training the plants under the roof remove portions of flowering wood down to the growth buds. These, if not cut away, only die back and disfigure the plants. This is all the pruning that the plants really need, unless the wood is becoming too crowded, when it is better shortened back than laid in.

Roses.—These are liable to be infested with scale when grown under the roof of houses occupied with plants that are subject to these pests. The best means of cleaning them is to syringe them after the completion of their growth with petroleum and water. They will bear without injury 1 oz. to each gallon of water. The foliage, or some of it, may fall afterwards, but this proves no detriment to the plants. Nearly all varieties in cool houses that are used for climbers, *Maréchal Niel* excepted, may have puny wood cut out and unripe ends of the shoots removed. The plants, through the lower temperature, will naturally go to rest, and light will be admitted to the occupants below.

Early Flowering Chrysanthemums.—It is a mistake to leave the propagation of these until the spring months. The season of growth is then too short for them to develop into strong specimens with a good number of shoots capable of yielding large fine flowers. Such varieties as *Madame Desgrange*, with its sports, as well as others, have now plenty of good sturdy cuttings upon them, and if inserted at once in a temperature of 50° to 55° they will not be long before they are rooted. Directly they are rooted they should be potted singly if not inserted in small pots to commence with. They should also be placed after they are potted in a cool house where frost is excluded. The point of the plant should be removed as soon as growth has commenced.

Tuberose.—Any plants that have their flower stems visible should not be in a lower temperature than 55° to 60°. They will advance freely in this temperature and open their flowers, which will be of the purest white. When developed in too low a temperature the flowers are frequently greenish yellow in appearance at this season of the year. Tubers that were potted a short time ago and plunged in heat should have the material removed that was used for covering the surface of the soil to prevent evaporation until growth and root activity had commenced. Water may now be applied whenever the soil approaches dryness. By no means allow them to become dry now that the roots are extending freely. The plants should be plunged as near the glass as possible to prevent the foliage drawing up weakly.

Abutilons.—These will flower throughout the winter if kept in a temperature of 60°. In a low temperature the buds fall in a small state or the flowers before they expand. If the plants are to continue flowering they must be encouraged to grow slowly. Where they are grown in pots it will be necessary to feed them with weak stimulants every time water is needed, or apply artificial manure to the surface once a fortnight.

Solanums.—A few plants that may have done duty in the dwelling house and lost their leaves may be pushed into growth for yielding cuttings for next season's stock of plants. Cuttings strike freely at almost any season in heat, and to obtain well developed well herried plants it is important to make an early start. By early striking hushy plants are ready for their final shift fully two months earlier than those raised from cuttings produced during the early months of the year in a natural way.

Cannas.—These are very useful for decorative purposes. The dark coloured foliage of several varieties is very effective either for groups in the dwelling house or conservatory. A few plants that have enjoyed a good period of rest may be started into growth in heat. As soon as they are moving divide them, and place each growing portion singly in 5-inch pots.

THE BEE-KEEPER

NOTES ON BEES.

BEET SUGAR AS FOOD FOR BEES.

At page 409 "Felix" says, "5 or 6 lbs. of good beet sugar syrup should at once be given as rapidly as the bees will take it." Now it is not a question of doctors differing, but one of bees. My bees and those of my neighbours seem to have a distaste for raw and beet sugars. Moreover, when they do take it, the bees invariably become unhealthy if it is consumed during the winter. Beet sugar is not so profitable as sugar from the cane, being lacking in saccharine matter, and although cheaper by the pound is the most unsatisfactory for the table or the bees.

He also says, "On the hive, then, which it is intended to feed, a piece of perforated zinc should be placed, large enough to take the place of the cover previously in use on this zinc; a piece 4 inches square is a good size, and can be used either on a straw or wooden hive." It will be observed from the above that the zinc

lies flat upon the top bars, so that when a small mouthed bottle is used very little surface is exposed for the bees to feed from. When feeding with the bottle I use a block of wood 2 or 3 inches deep, having a hole on the upper side sufficient to receive the neck of the bottle, and a smaller one on the under side about half an inch deep, the difference in the size of the holes being to leave about one-eighth of an inch of bearing for the neck of the bottle all round. In this way the bees have easy access to the syrup, and there is room for the bees to cluster and keep up heat at a time when it is absolutely necessary.

The best of all feeders is the frame feeder, having the trough nearly all its length in the top bar, and which places the syrup close to the bees. Weak hives may be fed with safety during winter with such a feeder, and the fountain above having a pane of glass on one side, a glance shows how the syrup is being consumed. The same fountain with a narrow tin scoop can be used as a bottom feeder, which, when the drawbacks of hives being capable of top feeding is taken into consideration, is the most natural and best way to feed bees, provided always no syrup is allowed to stand during the day.

UNSEALED STORES.

There is a general opinion amongst bee-keepers that stores should be fully sealed at this season of the year. Bees, even during very cold weather, will seal the greater part of their honey or syrup; it is natural for them to do so. But at no time do they seal it all, there being mostly some weeks' supply unsealed near the bees. It is when this unsealed honey gets exhausted during a period of protracted cold weather that bees are likely to die from want; but happily in this country the weather is seldom so severe as to preclude them from replenishing their wintering cells near the cluster from the sealed outer combs, which are always the first ones the bees empty. The so-called winter passages through the combs and above the bars with candy are inimical to the welfare of bees. The natural passages left by the bees are always round the ends of the combs, and we need not enter into any scientific explanation of the fact.

Bees always make an attempt to close overhead passage ways or spaces, and sometimes build their combs so close at the top as to touch each other. Why then should the nature of the bee be outraged by comical devices of man? I repeat again, to successfully winter bees keep them in single-cased hives well protected on the sides and on the top with an ample covering of well dried meadow hay, and over all an impervious roof projecting well over the sides and free from the covering above, so that the air can pass freely around and over. In addition to this have a properly constructed ventilating floor and a narrow entrance, and the bees, while honey is in the hive, will neither die from want nor cold, and the upper floor will never require cleaning.

THE WEATHER.

The weather keeping exceptionally fine, the day temperature being as high as 56° Fahr., and the bees, especially the Punic ones, are busy carrying pollen, the principal flowers being *Arabis*, *Wall-flower*, and *Charlock*. At the same date last year the bees had been confined to their hives for more than a month, so that whether the coming winter be a severe one or not they will have a shorter one, and from being stronger in numbers and having the daily flights are all the more promising for the bee-keeper. Should the spring and summer of 1890 be favourable a large harvest will be secured.

DECAY IN HIVES.

Many bee-keepers are realising the fact that double-cased hives are neither the healthiest nor the most lasting, and I have no doubt many will not renew them, preferring the more healthy and cheaper single-walled hives in the future.

STANDS.

These should be detachable (my own are mostly so) and of angled iron, which when tarred does not rust readily. Some people

are careless in not guarding against the decay of the legs of their hives, which they readily do when placed upon the ground without having a piece of slate or similar non-porous material beneath; but even when this precaution is taken decay soon sets in, through the capillary attraction of wood. Although slate is non-porous, still the wood absorbs and draws up the water as it lies between the foot and the slate, which is always present to some extent when the bodies rest upon each other.

To reduce the attraction of the feet of the hive for water place a small pebble or pyramid of lead beneath the foot, so that it will have little bearing; or drill a hole in the centre of the foot of a size to hold firmly a small marble bedded in white lead, so that it projects about a third. This will entirely prevent premature decay in the feet of the hive, and frequent coating of tar or creosote will further lengthen their days.—A LANARKSHIRE BEE-KEEPER.

GLASS SECTIONS.

SOME time during last autumn your correspondent, "A Hallamshire Bee-keeper," I think, promised to lay before your readers the secret of how to make glass sections as quickly and economically as wooden sections. I tried to draw this secret before he was prepared to part with it, and failed. I set to work, and with the aid of the glue-pot and some stout note paper succeeded in making a few dozens; but I would not like to tell your readers how long it took me to make them, nor how much they would cost per dozen if my time was charged at the rate of wage required by a dock labourer for overtime; nor shall I describe how gingerly they had to be handled and the difficulty of getting them to stand upright and fixing the foundation in them. In searching for something stronger than paper a friendly stationer suggested vellum tape, which was an improvement, but still it failed in keeping the sections square and rigid. Here the matter rested. The sections were put on the hives, in due time were filled with honey, and pleased everyone who saw them. Amongst others, with an eye to business, I exhibited the latest novelty to the representative of a local grocer. This gentleman informed me that a neighbour of his also made glass sections, and added that he put them together with tin, and that he believed he was going to have or had got a patent for it.

I thought of tin, and at night I made a glass section, which turned out to be identical with our friend's patent. Some weeks after this at a local flower show I came in competition with glass sections and met the enterprising patentee. My tin-and-glass section was produced, and I was most graciously told that he would forgive me for making that one, but in the most solemn tone ever assumed by patentee added that I must "never make another one." Now, I have every respect for patents, and wish to give all credit to the gentleman who was shrewd enough to think of tin for making glass sections and was enterprising enough to patent his invention. I have not yet seen it advertised in this Journal, nor in our local papers, but from what I hear they will add something over a shilling a dozen to the price of the honey without the glass. I hope I have been misinformed, as that will prevent their ever coming into general use when compared with wood sections at 2s. 6d. per 100.

Now, I would like to ask "A Hallamshire Bee-keeper," or any who are versed in patent laws, whether I can make these for my own use and place the honey in the market in the usual manner in them without being sued by the patentee? If I cannot do this can I with safety use tin in another and simpler way for the same purpose? as I suppose it is quite possible to improve on even a patent.—A SUSSEX AMATEUR.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post, and we do not undertake to return rejected communications.

TO CORRESPONDENTS.

In consequence of the extraordinary pressure that will be experienced during the Chrysanthemum season questions cannot be answered with the usual promptitude, and especially those arriving after Saturday. See notice below relative to the naming of fruit.

Chrysanthemum Sport (T. C. W.).—The bloom you send is very poor one, and if that is a fair example of the sport you may safely discard it, as it would be worthless.

Chrysanthemum Amy Furze (A. C.).—It would be much better if the catalogue were adopted as a standard of reference generally, but in the case of societies which are not affiliated this cannot be enforced, and the judges have to be guided by the conditions in the schedules, or in the absence of any stipulation they would be guided by the character of the blooms.

A Curious Error (F. D.).—The description to which you allude of Mr. Prentice winning all the first prizes in the fruit classes at East Grinstead "with very fine blooms," is both curious and amusing. The error is obvious, and the word "blooms" ought to have been printed "examples." It is not very surprising that the heads of reporters are filled with "blooms" at this period of the year, but the hurly burly will soon be over.

Chestnut Trees Dying (Twenty-years Subscriber).—If there is no noxious matter in the soil, but a fungus, as you suggest, is the cause of the misfortune, you cannot do harm by syringing the trees with a mixture of softsoap and petroleum, dissolving the soap at the rate of 2 or 3 ozs. to the gallon of boiling water, stirring in briskly while the solution is hot a quarter of a pint of the oil. If this fails try sulphide of potassium, following the directions that accompany it from the chemist.

Hibiscus Cooperi Treatment (T. T.).—The plants may be rested, allowing them to become tolerably dry during the winter, but not so dry as to cause the wood to shrivel. In spring they require a little cutting in so as to bring them into shape, and starting in a brisk moist heat, afterwards affording plenty of heat and water throughout the summer. When the plants break repot, keeping shaded until re-established. A compost of peat and loam, both fibry in equal parts and not broken too small, with the addition of a sixth each of sand and charcoal, suits this plant perfectly. The plant generally is best treated as an evergreen—i.e., not dried off in winter, though rested as other stove subjects. Strike some cuttings in spring and grow them on, young plants being more satisfactory than old stunted plants.

Destroying the Eggs of the Winter Moth (T. L.).—We are not aware that there are any means for the destruction of the eggs of the winter moths, the most widely destructive of which is *Cheimatobia brumata*. The moths appear between the beginning of October and end of December; the females being wingless must crawl up the trees to reach a suitable situation for laying eggs, or they may be carried from one place to another by the males, which are winged. That something of this kind occurs is evident from trees being infested with the caterpillars which have their stems protected by a sticky ring of grease which no crawling insect could possibly pass. The eggs are laid in the crevices of the bark and other places suitable for protection. The larvæ eat at first into the buds in early spring and completely destroy the prospect of fruit, and as the leaves enlarge the larvæ spin two or three leaves together and feed between them. When full grown the larvæ lower themselves to the ground, burrow, and form cocoons, in which they become pupæ at the end of May or the beginning of June. As to remedies, the best is that which aims at the destruction of the females. This is effected by wrapping the stems of the trees with a strip of Hessian about a foot wide, and smearing it with grease, tar and grease in equal proportions answering; but whatever is used it must remain soft and sticky, and be renewed as necessary to keep it in that state. Another means is to shake the trees when the larvæ is nearly full grown, cloths being placed on the ground to receive them, on to which the larvæ will fall, or let themselves down by silken threads, when of course they may be destroyed. The stems also should be smeared with some sticky substance to prevent the re-ascent of any larvæ falling and not being destroyed. After the larvæ pass into the pupa state, the only means that can be employed against them is to dig the ground occasionally so as to expose them to the discerning eyes of birds, which make quick work of the pupæ. Those means of riddance do not apply to your question of destroying the eggs, which we fear must from the care taken by the females in their deposition, be precarious, but we see no reason why means should not be taken when the larvæ are about to issue from the eggs, or before they have eaten into the buds, to combat them. Probably a solution of Paris green would be effectual, applying it at such time in March or early April as the buds commence to swell for expansion, mixing 1 lb. of this substance with thirty gallons of water. It may be applied with a syringe or garden engine, well wetting all the parts. It must be used with great care, kept from vegetables, and the operator must have hands free from sores or scratches, as it is very poisonous.

* All correspondence should be directed either to "THE EDITOR" or to "THE PUBLISHER." Letters addressed to Dr. Hogg or members of the staff often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

Violets in Frames (V. S.).—Violets to flower freely in frames during the winter are prepared by planting small divisions or rooted suckers in April a foot apart in rich soil and a suitable position, watering them as required during the summer to ensure fine plants, and shortening the runners of those that need it, keeping the beds free from weeds. In September or early October the plants are taken up carefully and planted in frames that have until then been devoted to Melons or Cucumbers; or a gentle hotbed is made of leaves chiefly, and about 3 feet high. This is covered with a good soil about 9 inches thick, and made rather firm for the plants. They are well watered immediately after planting, and carefully afterwards. The frame is kept rather close for a few days, and then judiciously ventilated according to the weather, all decaying leaves being promptly removed. The plants so treated become established by the winter, and flower freely. The sides of the frame are protected with manure in severe weather, and the glass covered with mats and straw. If Violets are planted in beds of convenient size, and frames are placed over them, the plants flower freely. If your plants are so arranged that frames can be placed over them you would probably have better results than lifting the plants; but if they must be lifted and transplanted the work should be done at once, planting them so that the leaves of one plant nearly, but not quite, touch those of the others.

Clematis indivisa in Pots (Amateur).—This free-flowering and useful Clematis can be readily grown in the way you suggest, as shown in the illustration (fig. 57). The shoots require to be trained over a

FIG. 57.—CLEMATIS INDIVISA.

trellis, which they will cover with fresh green foliage and abundant pure white flowers. It is of easy culture, and needs little attention beyond keeping it free from insects.

A Caution to Gardeners (W. J. G.).—The only letter we have received from you on this subject is the one dated November 14th. The reports of the County Court cases against Mr. Mark J. Freeman at Exeter by gardeners are remarkable, and the evidence extraordinary. The defendant's answer to the question, "How many gardeners have you had the misfortune to differ with and peremptorily discharge in the last twelve months?" was "I really don't know." That he was wrong in his hasty action is clear from the cases being decided against him. He will probably continue advertising for gardeners, and it is only right that men should know of this litigation. We have no fruit from you, and as you may see from the notification below, Dr. Hogg is not in London to name fruit at the present time.

Chemical Manure (Disappointed).—If you refer to the mixture of superphosphate of lime, muriate of potash, and sulphate of ammonia, it is undoubtedly good when rightly used. It is doubtful if you have read carefully, and you appear to have departed seriously from the instructions. As you may see if you read the remarks again, the mixture is recommended as a supplement for, not an addition to, good farmyard manure, and if you used both they were not needed. If you used no farmyard manure you still erred in applying the mixture, as you say, "all through the season." It was only recommended to be used once, then if crops did not grow fast enough, to scatter amongst them a little nitrate of soda. You have possibly used ten times as much of the manure as is advised, therefore in extraordinary excess, hence the pithy condition of your Celery. The mixture is not the less good because of your misinterpretation of the instructions, which seem plain, and are founded on many years of experience.

Names of Plants.—We only undertake to name species of plants, not varieties that have originated from seed and termed florists' flowers. Flowering specimens are necessary of flowering plants, and Fern fronds

should bear spores. Specimens should arrive in a fresh state in firm boxes. Slightly damp moss, soft green grass or leaves form the best packing, dry wool the worst. Not more than six specimens can be named at once, and the numbers should be visible without untying the ligatures, it being often difficult to separate them when the paper is damp. (*Inquirer*).—The Bromeliaceous plant is Tillandsia carinata, which is known to some authors as Vriesia brachystachys. (*W. R. O.*).—1, Cestrum aurantiacum; 2, Stokesia cyanea; 3, Asplenium flaccidum; 4, Cyrtopodium insignis.

Names of Fruits.—The names and addresses of senders of fruit to be named must in all cases be enclosed with the specimens, whether letters referring to the fruit are sent by post or not. The names are not necessarily required for publication, initials sufficing for that. Only six specimens can be named at once, and any beyond that number cannot be preserved. (*H. E.*).—1, Beurré de Capiaumont; 2, decayed, possibly Beurré Clairgeau; 3, Green Yair; 5, Comte de Lamy; 6, Nec Plus Meuris. The Apple is Golden Spire. (*J. G.*).—1, Beurré Diel; 2, Beurré de Capiaumont; 3, Autumn Bergamot; 4, Beurré d'Amanlis; 5, Napoléon. (*G. R.*).—The Pear is a small Beurré Diel. The Ferns are much withered; both appear to be Adiantum cuneatum; our reply about Beet is in the affirmative. (*A. T. W.*).—Fearn's Pippin.

* * In consequence of Dr. Hogg's absence from London fruit sent to this office cannot be named by him during the present month.

COVENT GARDEN MARKET.—NOVEMBER 20TH.

THE FLOCK IN WINTER.

THE LAMBING.

TAKEN from the Dorsets onward through tup breeders flocks to those of the ordinary farm flock, the lambing season may be said to extend almost throughout winter into spring. No fixed rules can therefore be laid down for it, but useful hints may certainly be given for general guidance, especially of home farmers, with whom the time of lambing should always be one of expediency and not of necessity. By expediency we mean that the lambing should be so timed that there may be an ample provision of green food ready for the flock in unbroken successional crops as required. To ensure this there must be a certain proportion of arable land, and we question strongly the wisdom of laying down so much land to permanent pasture as we have seen on some estates. Extremes seldom answer, and we think farmers in the great corn-growing districts, and those in a purely grazing part of the country, might compare results, and discuss the reasons of success or failure in flock management with much mutual advantage. No discussion, and nothing we can say or write, will be of use to those who are ignorant of the actual requirements of a flock, and who absolutely court failure by reckless mismanagement. For example, we found a ewe flock which came under our care some years ago in April was upon poor pasture by day, and was driven to folds upon a bare fallow at night without any provision of trough food for the ewes, that while suckling lambs were thus kept fasting some thirteen hours, and were driven back to the pasture in a state of exhaustion. We know another flock at the present time for which indeed there is an abundant store of roots, but there is no green food for next spring except pasture, which is practically uncultivated, the only manure it has being that derived from unfolded sheep. If the spring proves a late one that flock is bound to suffer a certain amount of privation.

Pasture under systematic cultivation may undoubtedly be made to answer as well for the flock in early spring as almost any green crop on arable land; but unfortunately such pasture is the exception and not the rule. It might be managed this season by folding if begun at once, as a tolerably strong and early growth of herbage would then be insured, and there would be a considerable subsequent improvement in both respects if the pasture had an annual dressing of chemical manure in February. Too much stress cannot be laid upon this important matter, as it is quite certain that pasture generally would carry several more sheep per acre, and be available for the flock much earlier in the year if cultivated with as much care as arable land.

Valuable as rich pasture undoubtedly is, it cannot be regarded as a substitute for Rye, because that is by far the earliest of all green crops, and be it remembered that even Rye is much earlier on rich well drained soil than upon cold poor land. Rye is, therefore, an indispensable auxiliary crop for the ewe flock. Winter Oats, Winter Barley, Italian Rye Grass, Tares, and Trifolium incarnatum, where it will answer, all follow in useful succession. Before turning from spring green crops for the flock we would call particular attention to the early growth of Perennial Rye Grass. We have a large field of it which has been very valuable for early grazing, and its early growth in some new permanent mixed pasture renders that pasture much more useful for the flock in early spring than an old pasture adjoining it which is deficient in this much-abused, much-praised Grass.

Every home farmer should have a lambing yard opening upon good sound pasture. Such a yard by no means involves a heavy

outlay. It may be made in an angle of farm buildings with a wall or boarded fence on the other sides. A low lean-to roof right round the interior wall or fence, and two or three cross fences with span-roofs afford the shepherd ample means for the construction of pens, and to shelter the entire flock as may be necessary. We recommend such yards both as a means of saving time and expense, and avoiding the annual construction of temporary folds, which are in the end much more expensive, and hardly ever answer so well. A really good shepherd is invaluable, and he should have all reasonable assistance both in the preparation of the fold and pens, and in the carting of food. Under good management there will have been a sensible exercise of foresight in the storage of roots and fodder close at hand for lambing. The shepherd must live with the flock then, and he should have a sufficiently commodious and comfortable hut for his accommodation. We allow the shepherd 6d. per head for all the lambs in healthy condition at weaning time. This acts as a healthy incentive to exertion, and is entirely in the master's interest. It is money well spent and well earned, and we have found the plan answer better than a high rate of wages without it.

(To be continued.)

WORK ON THE HOME FARM.

A wet October brought work on the land to a standstill, but so far November has brought us fine weather, and capital progress has been made with Wheat sowing, while forward crops of winter corn look exceedingly well, and the quickly raised cry about arrears of work and land to be left unploughed till spring is as quickly hushed. Farmers are said to be notorious grumblers, but we generally find that those who are loud in complaints of bad seasons and hard times are not the men who strive most to improve their practice and see if more cannot be done with the land. We would urge upon every farmer the importance of careful thought about the work and its object on his particular farm during the next eleven months. No doubt Barley is the most profitable grain crop now if it is really well grown, well harvested, and not forced upon the market out of condition. But if repeated trials have shown Barley to be an unsuitable crop for certain land, why it is simply suicidal to keep on sowing it. Upon a certain heavy land farm in hand we have gradually curtailed the Barley area, and extended that of winter corn simply because it answers best. The one difficulty about this change is to convince those interested that Wheat may be grown to profit in the same field year after year. We know men now agents of large estates who boldly proclaim their ignorance of scientific farming by outspoken expression of their disbelief in chemical manures. Such men will certainly one day find they are left behind in the race, for science and practice are daily becoming more united.

Upon all heavy land as much rigging as possible is being done, not only for root crops, but also for spring corn. Full reason have we to like the plan, for the land becomes so softened by its thorough exposure that we are able to push on spring work long before we could do with ploughing on the flat. Everything that can wait without material harm must give way for ploughing, one acre of land ploughed now being worth two left till spring. This, and getting superfluous water from the land speedily are the most important things now next to the finishing of winter corn sowing, which ought to soon be done with upon every farm.

REMARKS.

- 10th.—Cloudy early; fine and generally bright day.
 11th.—Cloudy early; mild, dull and damp day.
 12th.—Bright and fine in the morning, sun shining through hazy cloud in afternoon.
 13th.—Fog, rather thick till 11, then sun shining through very slight fog.
 14th.—Rather dense fog, gas necessary almost all day.
 15th.—Cloudy early; sunshine from 11.30; misty evening.
 16th.—Overcast all day, very dark for two or three minutes about 0.15 P.M.
 High barometer; cloudy nights; fog and damp air, but no actual rain, the 0.01 inch on 16th being due to wet fog.—G. J. SYMONS.

SPIRÆA JAPONICA.

NEVER perhaps in the history of this country have so many schemes been advanced for cropping land to prove remunerative as at the present time. Fruit-growing is a general topic of conversation, and we hope that good will result; in fact, we are confident on this point, for the subject has advanced to such a stage that it will not be allowed to fall again into the background. While our attention is directed to a subject of such national importance as the production of our own fruit, there are many who have land that will not be able to enter into this enterprise, and might do worse than consider the culture of other plants and roots that we have to import annually. The *Spiræa* is one of those that can be grown as well in this country as on the continent. At the present time we rely almost exclusively on imported plants, and this is to be regretted when equally good clumps could be grown at home. I do not for one moment think that it would pay those who live in the neighbourhood of towns where labour and land are dear to produce those they need for growing in pots for the market or for supplying cut flowers. But there is abundance of land of a light sandy nature near our coasts, and extending a few miles inland, that is now growing nothing but coarse grass and weeds which I have no doubt could be obtained for a low rent per acre, and could soon be rendered sufficiently fertile to grow these plants to perfection. To set aside what we may at present regard as waste land, there is plenty under cultivation that would be suitable for these *Spiræas*, though occupied at the present time with crops that do not yield one-half the return that could be thus obtained. As growers have relied so long upon continental plants they might be prejudiced at first against those grown here, but this could be quickly overcome by proving that they would flower profusely. All that is wanted are good clumps that will throw up plenty of large bold spikes of inflorescence.

The reason sandy soil is advocated is because it is easy to work, and quickly rendered fertile by the addition of manure. Planting and lifting could be done at almost any time, and for the latter the soil could be shaken out of the roots so much easier than soil of a heavy or moderately heavy nature. This is not all, the crowns would ripen earlier and better on light than heavy land. Light sandy soils are rarely, even during the driest of weather, destitute of moisture. While they appear dust dry on the surface they are usually moist below, a condition that would suit these plants admirably. We have abundance of land in this country very similar in every respect to that upon which they are grown in the neighbourhood of Ghent.

A large stock of plants could quickly be obtained when once a start was determined upon, and it is almost needless to enter into particulars how a stock could be raised and suitable plants for forcing produced without loss of more time than is really necessary. In nearly all undertakings some time must elapse before a return could be looked for, and the cultivation of *Spiræas* is no exception to the rule. The best, perhaps, and unquestionably the cheapest method of raising a stock quickly would be to obtain from some large grower of flowers for the market his stock of plants after he has cut the flowers from them, which plants in the majority of cases are thrown out. Any grower would rather dispose of them for a trifle than throw them away. These if planted thickly together in rows until autumn would be suitable for cutting up for stock. If

they could be left until the autumn following, a larger and better stock would be at hand to start with. Plants that flower profusely outside one year are in the best possible condition for lifting in autumn, cutting up and planting for forcing in the following year. After the plants flower weak crowns are produced, and these need one clear season's growth in which to attain a flowering size.

Spiræas placed out thickly together after forcing, even if left until the second autumn before they are divided, have seldom any but small crowns. Being planted closely together prevents the crowns developing sufficiently. When lifting for forcing there are generally some clumps that are not strong enough for flowering, and these are reserved for dividing and planting again. When good sized pieces are planted suitable portions can often be cut from them, and do well for planting for the next year's stock, but if the clumps were grown specially for the market their appearance would be destroyed if cut at lifting time.

Stock plants may be lifted at any time from the end of October or after the foliage has died away, and may be divided ready for planting. Roots that have flowering crowns may be cut very small and planted out 8 or 9 inches apart each way and allowed to flower. The crowns will increase rapidly after flowering, and be good for planting in autumn 1 foot apart and 14 or 15 inches between the rows. Small roots to start with generally make the best shaped clumps. The roots selected have seven or eight crowns each, and are planted as the work of digging the ground is proceeded with. The soil is firmed about them by pressing it with the foot after the clumps are placed into position. The crowns are as near the surface of the soil as possible, being only just covered. Manure is spread on the ground and dug in as the work of planting proceeds. Old manure, or that employed with leaves for hotbeds, is preferred.

The position selected should be an open sunny one, and the ground in the early part of the season must be kept free from weeds. After the plants begin growing the hoe should be frequently used. It encourages rapid growth early in the season, which is a decided advantage in the development of large crowns early in the autumn.

For years we have prepared plants for forcing in the way advocated, and have never been disappointed with the manner in which they have flowered; in fact, they have been forced as early and produced as many flowers equally as fine as any we have been able to obtain from imported clumps.—NORTHERNER.

THE ARRANGEMENT OF COLOURS.

COLOURS may be divided into two classes, the warm and the cold. Warm colours are scarlet, red, crimson, pink or rose, yellow, and orange; cold colours are blue, purple, lilac, and white. Now, if these colours are all mixed indiscriminately, without any regard to effect, though the garden will undoubtedly be variegated and mottled enough, yet the pattern will be confused, and except by chance there will be no breadth or depth of colour for the eye to rest upon. We shall much sooner be weary of looking upon such a scene, where every part presents the same discordant features. This was the great defect of the regularly mixed flower border. The eagerness with which the more modern fashion of grouping masses of colour has been taken up and followed by the owners of gardens proves that the association of colours in harmonious arrangement is felt to be a good desirable to be attained, and yet how often is this desideratum left to chance! The gardener having plants, of colours various enough in all conscience, makes an arbitrary selection. His resolve goes no further than this—"I will have this bed scarlet *Verbenas*, that bed purple *Petunias*, the other yellow *Calceolarias*; this little bed shall have blue dwarf *Lobelias*, that large one blue *Salvia patens*, a third scarlet *Salvia fulgens*, a fourth scarlet *Pelargoniums*; yonder little one shall

hold some white Bellflower ;" and so on till all the beds are filled with larger or smaller patches of colour ; but the mixture is quite as bad and as ill associated as the old mixed flower border.

Now, the merest tyro amongst our readers who thinks at all about the matter will say this random way of laying on the colours of our flower gardens is anything but good taste. How is it to be corrected, is the question ; how shall we learn to avoid such errors ? Our answer is, By studying the affinities of colours, by having a ground plan of the garden, and arranging the colours on that plan previously to putting in a single plant. The brightest and warmest colour (scarlet) may be placed in the centre or centres, the next (red or crimson) surrounding it, with a bed or two of the less glowing colours (yellow and orange) intermixed with rose or purple. Then follow these with the colder colours of blue or purple, bringing them down to lilac and white. If this plan is followed, with some modification or softening, the whole will have that pleasing harmonious effect so desirable in garden scenery.

Contrasts may be followed sometimes, but not too often. Never imagine that one flower sets off another unless there is an approach to affinity between them. To follow the simile, the natural rose on the cheek of "the fairest of the fair" is more pleasing than the blackest patch, because it is more in harmony with the natural colour of the rest of the face ; hence the fashion of wearing patches as contrasts has disappeared, we trust, for ever. Study, then, the affinities or relations of colours, and never act to any extent upon that saying—a black will set off a white.

Where there are no beds to group flowers in masses the same principles ought to guide us in planting borders, or even shrubberies and Rose gardens ; let the colours gradually, as it were, melt away into each other. What a wide field is here opened to us of pleasant labour and delight. To what a great extent the true principles of arranging colours may be carried. These principles may be applied to the arrangement of a simple bouquet of four or five flowers, as well as to the magnificent array of floral objects in the large exhibitions. They may be applied quite as correctly in the flower border or beds of the cottage as in the largest conservatories and flower gardens of the royal or princely mansion. We might enlarge much on this fascinating subject, but other objects press upon us. Enough has been said, we trust, to induce both amateurs and cottagers to think on the effect of a better arrangement of colours previous to filling their beds and borders with flowers another season.

Rustic baskets and vases judiciously placed near to the dwelling house, either on the pillars of a low wall or on pedestals, on a terrace walk, or one on each side of the entrance to the house, they are quite proper and in good taste, if not too numerous or too large in proportion to the size of the garden or house. Vases to grow plants in can be had of almost any size and form from the different manufacturers.—AN OLD GARDENER.

GARDENIAS AND STEPHANOTIS.

My object is to describe as clearly as possible the cultivation these will succeed under when occupying one house, and especially is this recommended where economy of space is a consideration. It is common in most gardens to see the Stephanotis trained to the roof of a stove—a good place I admit where no other is at command. The plants to occupy the house under such dense foliage will, however, make weak sickly growth compared with those in an open position. Assuming, then, you have a low pit or small span-roofed house, the roof should be covered with wire trellis about 8 or 10 inches away from the glass, and 8 inches apart. The stage should consist of slate slabs, or oak boards 2 inches thick, and when placing them in position have room for free supply of water, as abundance of drainage is required. Thoroughly clean and white-wash the walls to completely destroy all insects ; prepare a compost of good loam and peat in equal parts, and to every four barrow-loads add 1 bushel of charcoal. Previous to taking it in place a layer of turf grass side downwards, then the compost about 4 inches in depth.

When this is done the Stephanotis should be planted at one end of the house in a mound on the top of that previously brought in ; thin and tie the growths to the wires, then give attention to the Gardenias, planting as recommended for the Stephanotis, for when growth commences roots will soon be seen protruding through the sides of the mounds. When such is the case add more compost, which will assist them wonderfully. Keep them syringed two or three times a day, and especially at closing time. A temperature of from 65° to 80° in summer, and from 60° to 70°, &c., in the winter, or even a little less, will not harm them. The plants are both subject to mealy bug, but there is no difficulty in keeping them clean when grown together if syringed once a fortnight with a mixture of warm water and petroleum, and then syringing them

immediately after with clean water. Little need be said in favour of their qualities ; as cut flowers they are especially adapted for bouquets and other decorations, and they command great favour on account of their fragrance.—R. KIRBY, *Oulton Hall, Leeds.*

WEeping TREES.

A BETTER name for trees of this description would be drooping, for they are trees the branches of which, instead of growing in the more general way upwards, send their slender shoots downwards. The Weeping Willow, the Weeping Ash, and the Weeping Elm are the most familiar examples of this mode of growth. In order to have handsome trees of this description it is necessary to graft or bud the weeping variety on tall upright species of the same genus. Choose such as have clean straight stems ; prune off all the small branches to the desired height, and if there are three branches near the top leave them on to receive, at the proper season, a graft on each. The tree will then sooner make a good head of weeping branches, and be equally balanced on each side.

June is a good season for budding upright-growing Willows, Ashes, Elms, Beeches, and Laburnums, as will make good stocks with drooping varieties. Should these buds succeed you will secure a growth early in the following spring. Should part of the buds fail the stocks will be in good condition to graft in the March or April following. These stocks should not be worked—that is, grafted or budded—till they have attained the height of 8 feet, or thereabout. There is no objection to 10 or 12 feet in height, but rather an advantage, especially in such strong and rapid growers as the Weeping Ash and Elm. By having straight stems of such altitude the trees will form a natural shady harbour, under which, when the weather is hot, chairs or rustic seats might be placed. For such weeping shrubs as the several kinds of Cytisus, and Roses that have pendant habits, stocks of lesser heights would be more desirable, and for this reason, that as they are grown chiefly for their flowers, those ought not to be too much elevated. From 5 to 6 feet will be quite high enough.

We have already alluded to one use to which trees and shrubs of this description may be applied—that of forming a leafy bower, as shelter from the burning heat of the sun in summer. They are also sufficiently ornamental to be very desirable. What is more elegant and graceful than a drooping tree, a Willow or a Birch, especially ? What more beautiful than the pendant Rose, its branches clothed with flowers of every hue ? Then the pretty Cytisus, either with purple or white flowers, is very ornamental in front of the shrubbery, in the middle of a bed of flowers, or planted on the lawn. As ornaments, then, in garden scenery, they are of use and very desirable. Some of them, and more especially the Weeping Willow, are very beautiful if planted near the edge of a piece of water. There they are quite in character, and the more so from the pleasing shadow they cast upon the water. No other kind of tree except, perhaps, the Cypress, is so well adapted as a memorial of departed friends. The faithful servants of Napoleon showed their attachment to their master by surrounding his tomb at St. Helena with the Weeping Willow ; and when they left the island they brought slips of those trees and planted them in their garden in "la belle France" as remembrancers.

The most extraordinary weeping tree we ever noticed is a common Ash (*Fraxinus excelsior*) of some 50 or 60 feet high, with a clean straight stem, had all its side branches pruned off to nearly the top of the tree. Upon the highest shoots some grafts of the weeping variety were inserted. They succeeded, and when we had the privilege of seeing them they had made considerable progress downwards with every prospect of doing well. A young Ash or Elm, or common Willow, may be growing in the shrubbery of an amateur or the hedgerow of a cottager's garden ; and though of themselves not uninteresting, they may be rendered much more so by grafting weeping varieties upon them. Thus the wonders of the grafting art may be shown in many an obscure nook throughout the land.—T. W. M.

LILY OF THE VALLEY.

THIS popular plant is so well known by everyone that no description here is necessary. It is in no way particular about soil, and it will thrive in sunshine almost as well as in shade, the latter, however, being generally selected for it. It does best in a substantial loam, or in any soils rich in humus—such as are obtained from decomposed leaves. It should not at any season of its growth be allowed to suffer from a deficiency of water. The roots and shoots grow so fast as to soon form a dense mass, and should therefore be lifted occasionally and divided, operating on a portion at a time. An annual dressing of manure over the crown in

autumn will be of great benefit to the plants. This plant, besides being grown in the garden borders, is in general demand for forcing. For this purpose it is best to obtain imported clumps or crowns as soon as they arrive from the continent if flowers are desired for Christmas.

Single crowns are preferable to clumps if early flowers are required. Of these from twelve to eighteen crowns may be placed in a 4 or 6-inch pot, using a compost of two parts turfy loam, one of leaf mould, and one of sand. The clumps may be managed in a similar manner. These should be well watered afterwards to settle the soil, and plunged in coal ashes or cocoa-nut fibre for a few weeks, introducing them afterwards into a temperature from 50° to 60°, still excluding light from the crowns. Supposing they are wanted by Christmas they should be brought into the forcing house, where a close atmosphere and temperature from 70° to 75° is maintained. They should never be allowed to suffer through insufficient supplies of water, requiring most when they are coming into flower; attention to this operation is very important. If desired for succession they should be introduced into heat every two or three weeks.—A. G. FRAMPTON.

IN THE NORTH.

HAVING business in several places just lately, I took the opportunity of paying a few interesting calls and taking a few notes, which you can publish or consign to the wastepaper basket. The first visit was paid to the well known and celebrated prizewinners amongst the Roses—viz., the Messrs. Harkness & Son. Their nursery is but a short distance from Leeming Lane Station on the branch of the North-Eastern Railway from Northalerton to Hawes. There I found the two brothers busy in their office. Time being short, in response to my inquiry as to where they grew their Roses I was soon shown some healthy well grown dwarfs, several thousands, to which Mr. Harkness proudly points, and says, "This is where we cut most of our blooms for the prize stands," and fine healthy plants they were, clean and sturdy. The soil seems to be of a sandy loam, and evidently suits Roses although so far north. I understand that they grow them better on the Manetti and seedling Briar, finding it suits some varieties to be on one and some on the other. There are many other plants grown besides Roses, such as herbaceous Pyrethrums and Violas, Polyanthus, Carnations, &c. I have several other notes, but they must wait.—A. J. B.

A COMING ROSE.

SOME seasons ago a young lady, Miss C. M., sowed just six Rose seeds, extracted from a heap that had attracted her notice. It was not a large sowing. Some of us have sown thousands of promising seed pods with very little result. Nothing, however, is like trying except succeeding, and hers has been a decided success. The heap was taken off good old Général Jacqueminot, but what the other parent was is quite unknown. The result of that sowing is a plant which has come into the hands of a well known Surrey firm, and which is being largely propagated. It is hoped it will next year come into commerce. It is said to be not unlike that grand old favourite, which even now and again asserts itself in the boxes, only much improved. More substance the one thing the General wants, and even more fragrance, the thing which has been sadly failing us in the new Roses of late years. The same firm have one or two other Surrey seedlings they hope will be heard of. I venture at any rate to predict a bright future for Miss C. M. when she makes her *début*. Let us hope the sullen Mole will appreciate his new neighbour, as Lord Byron says:

"The odorous purple of a new born Rose

Which streams upon his stream, and glassed within it glows."

—A. C.

THE CATERPILLAR PLAGUE.

ACCORDING to your courteously expressed request that I should place some communication in your hands on the very important subject of present prevention of winter moth laying their eggs on the fruit trees, I have pleasure in offering a few remarks. I fully believe that it is of the utmost importance to stop the ascent of the wingless moths by grease bands, or, at least, by sticky bands of some material which will hold the moths fast without hurting the bark of the tree. I have strongly advocated this in my annual reports—in my reports to the Royal Agricultural Society—and lately gave a special paper on the subject (headed Winter Moths—A Word in Season), in the number for October of *The Farmer's Magazine*. I quite agree with the importance of banding, and I believe we are all of one mind that unless the winter moths are stopped going up the trees there will be immense damage done next growing season, and I also consider that none of the various

methods of prevention suggested, that we know of at present, are so cheap, safe, and sure as grease-banding. But I certainly *do* think also that a little more attention should be given to the possibility of the outside of young trees being so much injured by grease (or deleterious matter mixed with grease) soddening into the thick bark and underlying layers of young wood, that it may be fatal to the tree. All of us probably who have attended to the matter know all about this, but in some cases a word of warning is wanted.

In the case of old trees with thick rugged bark, dead on the outside, probably even tar might be safely applied, for the layers of old bark lying between the tar and the wood immediately underlying the live inside bark would protect it almost as securely as would a layer of cork. I would give a word of warning in such cases not to smooth down the outside bark, as a correspondent recently told me he was doing, or results may be very bad indeed. If the tar or grease is of a nature that can readily pass into the tree, it is obvious that the minute cells of the wood and bark will be so altered that they will not be able to convey the sap, and the effect will be a dead band, or a band so injured as to be almost equivalent in bad effects to ringing.

I know only too well of this happening, and therefore I would strongly advise all growers to make sure that the grease is not mixed with tar, or residue of petroleum distilling, or too much caustic soda, or any other matter likely to burn or choke tender tissues. Failing the power to do this, the spending a little time in finding whose neighbours' trees suffered, and whose did not, from grease banding would be of use. I would also strongly draw the attention of those who have many quite young trees, to the method of banding now in use at the Toddington fruit grounds. This is to pass a band of the thin grease-proof paper round the stem; secure the overlapping edges by a strip of paste, and then lay the grease on in the manner advised by one of your correspondents, not with a brush, but with a flat piece of wood. If the paste does not stick at once, a twist of string round the paper, or of bass mat, and just tying the ends, secures it firmly. The paper prevents any grease, except what may run down, lying directly on the tree, and I am informed by Captain Corbett and Mr. C. Wise, with both of whom I had long interviews, that they consider this the best method of application.

With regard to birds, I should certainly think it was of great importance not to lessen the numbers of the more especially insect-eating kinds, such as various kinds of titmice, the nuthatches, and tree-creeper, in fact, most kinds, excepting the house sparrow, which does mischief by driving useful birds away. I do not myself feel so sure as some writers that the bullfinch is so very injurious, and would much like that, before condemning him, a careful post-mortem of contents of stomachs of a few specimens should be made, to see whether the abstracted buds had or had not a maggot within them.

I fear I have already written at too great length, and, therefore, do not now add anything regarding either measures of remedy when the caterpillars are present in summer, or regarding the winged moths now depositing eggs. But I should very much like to lay before your skilled correspondents a point which may be worth inquiry. In all the caterpillar troubles which have now been a very serious matter for some years, though I have had a great deal of communication from most of our fruit-growing counties, I have not had any that I can recall from Devonshire or Somersetshire.

I think that if attack had been bad it would have been reported to me; but if attack was not serious, what is the reason?

Is there a general difference in the method of treatment? Is it more general to have grass, as in some of the S.W. Gloucestershire orchards near homesteads—where presence of sheep, pigs, and poultry in their different ways lessen presence of coming attack beneath the trees? Or do the vast masses of Mistletoe and great beards of lichen, which, when I knew common Devon orchards, were considered apparently not to be objectionable, shelter insect parasites, and attract small birds' presence?—ELEANOR A. ORMEROD (in *Worcester Herald*).

SOME BRISTOL GARDENS.

AROUND Bristol there are many gardens of interest to the general observer, but in order to pay a visit to a number, or even a few of the most interesting, more time is required than many can afford to give up for such undertakings. Being on a brief visit to the "metropolis of the west," I was tempted to extend my journey outward that I might see what I could in the way of gardening pursuits likely to prove interesting and instructive, and in which I was not altogether disappointed. Being an Orchid and Chrysanthemum enthusiast, I wended my way to Springfield, the residence of F. W. Savage, Esq., Westbury-on-Trym, in which Chrysanthemums are very well grown on the large bloom principle. Between 100 and 200 are so treated, mostly Japanese and incurved. Among the former I noticed some capital blooms of Madame C. Audiguier, Jeanne Delaux, E. Molyneux, Comte de Germiny, Moonlight, Gorgeous, Baronne de Frailly, Carew Underwood, Mdlle. Lacroix, and Mr. Cannell, among many others, old and new. Some of the best of the incurved included Empress of India, Lord Wolseley, John Salter, Mr. Bunn, Jardin des Plantes, Lord Alcester, Emily Dale, Queen of England, Jeanne d'Arc, and Alfred Salter. The plants are arranged in a vinery so that each and every one comes well under notice, and this is greatly simplified in the dwarf character of growth. Some of the plants do not reach a height of more than 3 feet, although unstopped, while others range from 4 to 7 feet high.

Orchids are not to be counted in large numbers, but an unsatisfactory plant is not to be found among the various sorts grown. *Cattleyas* *gigas*, *Mendelli*, *Mossiae*, and *Gaskelliana*, among others, are represented by some very fine plants, which promise to make a good display in their season, judging from the vigorous growths and prominent flower sheaths. The *Laelias*, *Odontoglossums*, *Dendrobiums*, *Cypripediums*, *Oncidiums*, *Phaius*, and *Calanthes* each display good cultural treatment. A small piece of *Odontoglossum grande* was just unfolding unusually good blooms from three strong spikes, and *Calanthes* of the *Veitchei* and *vesutia* varieties are unusually promising, the flower spikes of which are the stoutest I have seen this year.

Eucharises also do well, and Mr. Edwards, the gardener, believes that to indifferent treatment may be traced the cause of the appearance of that undesirable mite pest. Frequent disturbance of the roots is avoided even with plants in small pots, for when they are furnished with a vigorous root action, encouraged by judicious applications of a stimulative nature, the mite has no chance to establish itself. Zonal *Pelargoniums*, both single and double, are allowed small pots only, and although they have furnished material for cutting for three years past, still the supply is maintained. Hard wood is more persistent in blooming, and is far more reliable to give a supply through changeable weather of the winter months than young yearly struck plants would be, and stimulants can be much more safely and effectively applied to older root-bound than to young plants.

Gloxinias are grown largely and well. Four one-light frames were full of healthy plants pointed out as having being raised from seed sown in February, and pricked out on prepared beds of fermenting material. About 6 inches of fine rich soil is placed in each frame, and strong growth is farther encouraged at the time when flower buds are forming by applications of diluted guano, a stimulant Mr. Edwards has much faith in. By growing them in this way there are chances of securing a stock of the very best, as all inferior ones can be discarded as soon as the first flowers are open. A houseful of these chosen ones must have been a fine sight, as I am told that from plants in about 7-inch pots as many as sixty or seventy flowers could be counted on each.

Some medium-sized bunches of *Raisin de Calabre* and *Lady Downe's* *Grapes* were still hanging in theinery, and provision is being made for a supply of *Peaches*, *Nectarines*, and *Plums* indoors, as a house in two divisions is almost completed. This is one of the lightest structures I have seen. Longitudinal bars are disposed so as to take glass squares probably 30 inches in length; these are fixed by copper clips, and none of the glass laps, but are fitted so perfectly that drip is unknown. This system involves a considerable saving in outdoor painting, as there is no woodwork exposed. A miniature lantern is raised by lever movement for providing top air; deep central-balanced lights are adjusted for giving abundance of front ventilation. Trees for the front are intended to be grown in pots, which will allow of the space being cleared in autumn in time for *Chrysanthemum* accommodation; those on the back wall are to be carried to the ridge of the three-quarter span-roof, which will allow of good depth for extension.

What has become an annual institution, and somewhat novel at Springfield, is an extensive decoration of the house and tables by the large exhibition blooms, and is given the title of a *Chrysanthemum* "feast," to which numerous guests are invited at a given date. Altogether the garden and indoor plants reflect much credit on its chief, who evidently is no novice in the various duties entrusted to him. From here I make my way by road and railway to pay a long promised visit to

MALMAINS,

Captain Belfield's well-known residence at Frenchay, near Bristol, being attracted thither more especially to see the magnificent collection of *Filmy* and *Tree Ferns*, of which I had heard a good deal. But no description, however lucid, could adequately describe the beauties and richness of the display of the *Todeas superba* and *pellucida*, the former figuring the most largely. Some fifty plants are to be seen which fill a house about 40 feet in length, every plant provided with abundant space to display its intrinsic beauty. They occupy large pots, and, if I remember rightly, each one stands on another inverted, and from their long standing, together with the moisture-laden atmosphere, cause a greenness of such density that moss covers many of the pots' surface. This condition, so objectionable with pot plants generally, becomes in this case reversed, as it generates a greater harmony with the dark green fronds of the *Ferns*. Efforts have also been made to furnish the walls of the house with seedling *Ferns*, but the atmosphere does not favour a permanent or continued growth from this source. I cannot say how long these *Todeas* have been established here, but the plants must be many years old, as some of the stems rise 3 feet or more from their pots, and are of large dimensions. They were collected and brought home by their owner, who is, and may well be, proud of the success which crowned his efforts.

In another large house adjoining are growing some *Tree Ferns*, probably 25 feet high, together with *Palms* and other plants, some of which were collected by the "Captain;" noteworthy among them being stately specimens of *Cyathea dealbata*, *Alsophila australis*, *Dracæna indivisa*, *Areca sapida*, *Kentia Fosteriana*, *Latania borbonica*, and the *Date Palm*, *Phoenix dactylifera*. These are arranged with excellent effect through the middle and sides of the tall span-roofed structure, probably 50 feet in length, through which the informal paths make a most exquisite promenade. The spaces beneath these veterans of the tropical forests are occupied with smaller plants of an evergreen character. No flowering plants are employed, nor indeed are they required, so plenty of space

is found for them in more suitable quarters. In the stoves are the usual flowering and foliage plants of large sizes, a division being set apart for *Ferns*, which consist principally of *Adiantums* and *Davallias* of exhibition quality and proportions.

Eucharises are a strong feature; one side of a large plant stove providing suitable accommodation for the goodly number of large healthy specimens, and which give good returns for attention bestowed. From twenty to thirty spikes are usually produced from each pot twice a year, and they seem to revel in the treatment they are subject to, and, fortunately, mite attacks are unknown. Orchids fill two houses. Among them are some fine specimen *Dendrobiums*, *Cœlogynes*, *Cypripediums*, *Cymbidium*s, *Cattleyas*, *Laelias*, and other species, many of them showing signs of improvement under the care of the recently appointed gardener, Mr. W. Rye, who for several years previous held the position of head gardener to J. Derbam, Esq., whose gardens were famous at that time from an exhibition point of view in the neighbourhood of Bristol. I must refer but briefly to one other garden which I had the privilege of inspecting—namely,

BROOMWELL HOUSE,

for many years the residence of W. Proctor Baker, Esq., whose late gardener was at one time one of the most successful growers of pyramid-trained *Azaleas*. At the time these were in perfection it was a custom with Mr. Baker to throw open the gardens and grounds for public inspection, but fashion has since changed, and the veteran *Azaleas* were disposed to give place to smaller and more useful material.

A good number of *Bouvardias* fills one house that for cutting will prove invaluable. Many are in 12-inch pots and form large bushes full of vigour. They are planted out for the summer months, which tends to save labour in watering, and their condition is all that can be desired. On the back wall of the stoves are trained two large plants of the seldom found but useful *Poinciana pulcherrima*, that furnish flower sprays almost the whole year when planted out, and under restricted pot culture it may be had in bloom for several months. At each end stand some very large and healthy plants of *Adiantum farleyense* 5 or 6 feet through. These are growing in a clayey loam, with only an addition of charcoal and sand for maintaining porosity, which appears to suit them well.

Some *Poinsettias* planted in shallow trays along the front of the stove will make an attractive display later on. The stems are bent and tied to one uniform height, which will bring their glowing bracts well within view, and also provide useful heads for cutting. In the same-house space is given up for *Orchids*, of which *Dendrobium superbum* is represented by some uncommonly fine growths, the largest being quite 6 feet in length and proportionately stout. *D. superbum giganteum* is also very well grown, and its extra large blooms are most attractive in the spring months.

The vegetable and fruit gardens each occupy separate positions. One thing that struck me as being uncommon in the latter was the system of utilising the walks economically and cheaply. *Cordon Apples* and *Pears* are planted at intervals of a few feet in pairs opposite each other, and trained on stout iron rods to form an arch, and when this space is filled wire is strained along so as connect one with another, lateral shoots being taken right and left and allowed to extend until the space is filled. By this method the ground can be utilised at a little cost, and it certainly adds to the interest of the garden as well as bulk in produce, and does not interfere with the convenience of attending to other parts of the garden as ordinary fixed archways do generally. The flower borders are planted with some choice varieties of herbaceous plants, and a vigorous specimen trained to a low wall of the showy *Clianthus puniceus* makes a pretty effect at its season of blooming. Much credit is due to Mr. Archer, to whom is entrusted the charge of the gardens to the satisfaction of his employer.—S.

FIRE HEAT AND DAMPING.

WHILST visiting an amateur friend of mine a few days since I was complaining how my *Chrysanthemums* had damped. He told me that as soon as he saw his begin to damp he turned on the heat in the house and well sulphured the pipes. My amateur friend has turned on the heat about twice a week since and has not had a single floret damp. I might say that when the heat was on he closed the house for about an hour. I think this would be worth a trial by large *Chrysanthemum* growers.—G. L.

STANDS FOR BLOOMS.

MAY I be permitted, through your columns, to inquire if the size of the exhibition stands for *Chrysanthemum* blooms as laid down by the National Society is generally considered the most suitable that could be devised for that purpose? At the late show of the Derby *Chrysanthemum* Association no particular size was imperative, but one exhibitor had his stands made to order in accordance with the sizes given by Mr. Molyneux in his book as the National standard, and they appeared suit-

able to the incurved classes, but for the Japanese were far too small, most of his blooms actually overlapping; and that exhibitor is not alone in thinking that but for this circumstance he would have been awarded first instead of the second prize he took in one of the Japanese classes. Can anyone say whether this experience is general, and, if so, whether there is any probability of the standard being raised?—INQUIRER.

CHRYSANTHEMUMS AT ANTWERP.

THE Royal Society of Horticulture and Agriculture of Antwerp celebrated the centenary of the introduction of the Chrysanthemum

CHRYSANTHEMUM MRS. JUDGE BENEDICT.

At the meeting of the National Chrysanthemum Society's Floral Committee, held on November 12th, Mr. R. Owen of Maidenhead exhibited a large collection of new Chrysanthemums, chiefly from American raisers and introducers. Amongst them were blooms of a large Anemone bearing the name Mrs. Judge Benedict, which attracted much attention owing to its distinctness and delicate colouring. The blooms were of good size, with a well raised and rounded disk of a soft yellow tint, the rosy florets of moderate breadth, even, and of a

FIG. 53.—CHRYSANTHEMUM MRS. JUDGE BENEDICT.

into Europe at an Exhibition held in the hall of the Royal Harmonic Society on the 17th, 18th, and 19th inst. Groups were tastefully arranged, but cut blooms left much to be desired both as to quality and staging. We have only space to say that Messrs. H. Cannell & Sons, Swanley, staged a good collection of Zonals and Chrysanthemums, including a dozen blooms of Etoile de Lyon, which caused quite a furore. A silver-gilt medal was awarded; and that in the amateur class the first prize, a gold medal, value 200 francs, was awarded to H. Vanderlinden, Esq. The second prize, a silver-gilt medal, value 100 francs, to J. Everaerts, Esq., both of Antwerp. The show was considered a great success.

delicate blush hue. The varieties of large Anemones suitable for exhibition are so restricted in numbers that any meritorious addition is most welcome, and we may expect to see the one represented in fig. 53 take a place amongst the best.

MADAME LOUISE LEROY.

We have had sent from Chilwell a spray containing several small and one good sized bloom of this promising white Japanese Chrysanthemum. The bloom somewhat resembles Avalanche in character, but it is more pure and clear, and its appearance suggests that if represented in the best form from selected buds, it might prove a rival to that

famous variety. The bloom before us is not quite 5 inches in diameter, but is one of the most attractive we have seen this year.

CHRYSANTHEMUMS AT WALTON LEA.

MR. W. KIPPS, gardener to John Crossfield, Esq., Walton Lea, near Warrington, is well known as an expert cultivator of Chrysanthemums, and with Mr. J. Wright judged the cut blooms at Birmingham. Mr. Crossfield kindly opens his gardens free to the people of Warrington, and on two days last week a constant stream of persons took advantage of the privilege accorded. The crowd was so great that hundreds could not pass through the conservatory, but had to be content with a view from the outside. Walton Lea is two miles from Warrington, and is as much famed for the specimen Hollies in the pleasure grounds, and the Camellias under glass, as for Chrysanthemums—indeed, the gardens are admirably managed throughout.

THE KINGSTON AND SURBITON CHRYSANTHEMUM SOCIETY.

THE annual dinner of this Society was held at the Sun Hotel, Kingston, on Saturday evening last. The President, G. C. Sherrard, Esq., J.P., occupied the chair, and in a most able address displayed the great interest he took in the Society. There was a very large attendance of members and visitors. The Treasurer, Mr. John Drewett, who is such a staunch friend of the Society, said that with one exception the receipts at the recent Show were greater than on any former occasion, and with the increased subscriptions the present year was the best financially since the Society was established. He was also able to state that another twenty-five-guinea challenge cup would be provided for competition next year. The proceedings were highly enjoyable throughout.

THE NATIONAL CHRYSANTHEMUM SOCIETY.

THE Floral Committee of the above Society held a meeting in the Royal Aquarium, Westminster, on Tuesday, November 26th, at 2 P.M., R. Ballantine, Esq., in the chair, and the following members were present—Messrs. W. Holmes (Secretary), E. Sanderson, G. Gordon, L. Castle, G. S. Addison, H. Cannell, R. Owen, J. Kendall, G. Stevens, C. Gibson, W. E. Boyce, and J. Wright. Numerous novelties were exhibited by Mr. E. Beckett, Mr. R. Owen, Messrs. Carter & Co., and others, and several were considered promising, the exhibitors being requested to show them again another season. Only one was regarded as worthy of a first-class certificate—namely, a handsome Japanese named Volunteer from Mr. E. Beckett, one of the best additions of the season. It has some fluted recurving or slightly twisted florets, of a soft clear blush tint, the bloom deep, substantial, and grand for exhibition purposes.

THE GHENT CHRYSANTHEMUM SHOW.

THE Ghent Chrysanthemum Centenary Exhibition was opened on November 24th, when we are informed that there was a good display of plants, but comparatively few cut blooms. Of the English exhibitors a gold medal was awarded to Messrs. J. Laing & Sons, Forest Hill, for a collection of cut blooms; silver medals were also adjudged to Mr. E. Molyneux for cut blooms, and to Mr. Payne for an album of coloured plates. A gold medal was also awarded to the National Chrysanthemum Society as "a token of regard" from the Ghent Society. Medals were presented to numerous continental exhibitors in the various classes.

LOCAL MUSHROOM HUNTERS.

"AM I right for Rockingham, Sir?" said an old man as he got into a L. and N.W.R. carriage at Peterborough, in which sat an occasional correspondent. Having assured the old man that he was adopting the correct means for ultimately reaching Rockingham, other questions and answers followed, and the old man declared himself to be a Mushroom hunter. This was such an out-of-the-way occupation that the occasional correspondent began to think that it would perhaps form a subject for the gallery of local industries, and, therefore, plied the old man with questions fast and furious. At first the replies were simple and interesting, but later on, as the train was approaching Rockingham, the Mushroom hunter began to have some suspicions that he was being "fished." It evidently occurred to him that the occasional correspondent was seeking information, probably with a view of starting in opposition to himself. His change of manner at once became noticeable. He lapsed into a most guarded reserve, and the only information he vouched was to impress his auditor with the masses of wealth which Mushroom hunters were everywhere losing, and himself in particular.

But he had a ready—before the rash suspicion seized his mind—furnished some curious information concerning Mushroom hunting. He was then on his way to purchase seven tons of the edible fungi. He would sell them again to ketchup makers. He anticipated he would have to give nearly £60 per ton for them, and was, therefore, about to incur an expenditure of £420. Seven tons of Mushrooms! Where in the name of the sweet champagne would anybody get such a mass of Mushrooms as that from? Then he explained how it was done. The Mushroom hunter had to travel long distances by train and on foot, and he was obliged to have a boy and a horse and cart dancing attendance upon him. He himself had during the past few months travelled over the greater part of Lincolnshire and Huntingdonshire. His plan was to leave his horse and cart at a certain point and work round to it. He would travel perhaps twenty-one or twenty-two miles by train, and then proceed to

walk across country, having previously arranged his route, and call at all shepherds' houses. Why shepherds' houses more than anybody else's? Because shepherds walked over more grass land than anyone else, and were more in the habit of collecting Mushrooms than any other class. He invariably found that shepherds had a tub for Mushrooms, but many of them would not sell them at any price, as they made ketchup themselves and sold it to a circle of local customers. On the other hand many were willing and ready to sell their Mushrooms, and would often indicate that "Shepherd So and So had a tub to sell." But how did the shepherds keep their Mushrooms until the "hunter" came? They could not keep them for more than a day or so. Unless the Mushrooms were quite fresh they were of no use to the "hunter." Many shepherds would get a stone or so of Mushrooms a day, and in such cases the "hunter" would find a good tub full. These he would buy, and either late that day or early the following day he would retrace his steps with the cart and take them away and put them on the rail at the first convenient spot.

Then you are always sure of a customer? Oh, yes, he could find customers for as many Mushrooms as he could get. One ketchup maker in Peterborough had received an order for making a stupendous quantity of ketchup for Messrs. Crosse & Blackwell, and he knew he had a ready market for Mushrooms there. He had no difficulty in finding customers for them in large quantities. But do these ketchup manufacturers all use real Mushrooms? Is there no such thing as walnut-limmings employed? In the factories in which he had been in they all used Mushrooms, as they were cheapest in the end. In some years they were much more plentiful than others. The present year was very bad. They were extremely scarce. He had been obliged to give as much as £60 a ton often this year, while in other years he had been able to purchase large quantities for £40 a ton. But it cannot be generally known that they are so valuable, or more care would be taken to collect or cultivate them? He supposed that people must know that they were valuable, for they were generally sold in the shops at 6d. or even 10d. a lb. How would it be possible for anyone to collect such a quantity as seven tons of Mushrooms altogether? They would have to be collected in the way he had indicated. Half a stone here, three or four stone there, and so on. Collectors had to give good prices for these small quantities, for shepherds knew their value, and it often happened that after paying all his travelling expenses, the cost of his horse and van and boy, the profits were not very large.

As Mushrooms, however, do not grow all the year round, the occasional correspondent questioned the "hunter" as to his occupation when Mushrooms were not to be gathered, and he replied that he then went hawking crockery with his van. But by this time his suspicions had become aroused, and he gave many assurances that Mushroom hunting was a "losing game," and that he had had quite enough of it, that this was his last season he would have anything to do with it, and much more to the same effect.—(Peterborough Advertiser.)

SALT FOR FRUIT TREES.

I NOTICE, in an interesting paper on Plums read by Mr. T. F. Rivers at the Horticultural Club, reported in the Journal, p. 439, that he states an American writer finds common salt very beneficial for promoting health and luxuriance of Plum trees, but that Mr. Rivers fears to apply it. He need not be afraid to do so in limited quantities, such as usually given to crops. As our soil is very deficient in soda, and finding it very beneficial for Strawberries, which contain a good deal of this in their composition, and other fruits likewise being partly composed of it, and thinking that canker might be a result of weakness of constitution, owing to the deficiency of some element of plant food required, and as I take care that they have an abundance of those commonly needed, this year I added soda also, by means of an application of common salt at the rate of 2 cwt. per acre over the whole of my fruit ground, which contains all hardy sorts of fruit, and many acres of Plums, and I have been so far satisfied with the result that I propose repeating the dose next spring, and probably will make it an annual thing. Of course massive doses would kill vegetable life.—WALTER KRUSE.

HEDGE PLANTS.

OF the objects on which cultivation is brought to bear there is, perhaps, none that presents a greater diversity in the results sought to be attained than that most indispensable of all fences, the hedge. Timber, brick and stone, with or without mortar, as well as the varied forms that wrought and cast iron are made to take, all more or less compete with the living hedge as a boundary between properties and protection against cattle, but the hedge still survives, and imparts a degree of clothing to a district which artificial objects fail to do, also in most instances affording more shelter than the hand-made structure has any pretensions to do. My object, however, is not to contrast the merits of a live fence with those of a dead one, but to ascertain which are the most suitable plants for hedges, and to point out how one that was brought before the public some years ago as likely to be useful for the purpose, has failed, and is now but rarely met with; in fact, it now only occurs in the back-shrubberies, or other out-of-the-way places. Before drawing attention to the merits of other plants let us take a glance at this, and

see how far it is entitled to the high character given of it many years ago.

MACLURA AURANTIACA, OR OSAGE ORANGE.

A deciduous shrub of rather formidable appearance in consequence of the prickles with which it is armed, neither is it deficient in habit nor in hardiness for the purpose of making a fence capable of withstanding cattle; but somehow it has not found its way into general use, neither am I acquainted with any extent of hedge formed of this plant—in fact, I am not certain that I have seen it used at all in this capacity for some years, when a hedge of it was pointed out some years ago in Kent that was fully exposed on one side at least to the tender mercies of sheep and cattle, and it seemed to answer pretty well, was well clothed with foliage, and in other respects was a formidable closely trimmed fence. It was clipped at about the usual height for Thorn hedges, and when I saw it (September) it was a good rival to the Quickset. My impression at the time, confirmed by what I have noticed of some single plants here, was that the later growths of the season do not ripen, even in hot dry summers. Growth continues so late that the tips rarely harden sufficiently, and, like the Fuchsia, always die off, more or less, during the autumn or winter.

The plant seems to be well furnished with branches, and an abundance of very formidable thorns, much more so than Quickset—in fact, when growing amongst other shrubs, I do not know of anything more likely to keep out intruders. The foliage also is bright, shining, and on the whole attractive, and the growth of the plant in all the cases I have met with is as rapid as need be wished for in a hedge plant. I have been told that in some parts of the Canadian Dominion it is used for hedges where the climate is too severe for the Quickset; so that we may fairly place it amongst the hardiest of plants. Yet there may be a difference between an English and a Canadian summer that may enable the Maclura to endure the winter of Canada better than that of this country; for in all probability the fine sunny autumns of North America ripen the tips as well as the Hawthorn ripens with us.—J.

EVENTS OF THE WEEK.—The National Chrysanthemum Society's General Committee will meet at Anderton's Hotel, Fleet Street, on Dec. 2nd, at 7 P.M., the Centenary Sub-committee having a meeting at 6.30 P.M. on the same evening. On Wednesday, December 4th, the National Rose Society's annual meeting will be held in the Horticultural Club Rooms, Hotel Windsor, at 3 P.M., and the annual dinner will take place the same evening. The usual sales by Messrs. Protheroe and Morris and Stevens will be held during the week.

— A **LANDSCAPE** gardener, who had gained no mean degree of fame in this country, **MR. ROBERT MARNOCK**, died in London on November 15th last, in his ninetieth year. Mr. Marnock was early associated with the Sheffield Botanic Gardens, which he designed; subsequently he also laid out the Regent's Park Botanic Gardens, one of his principal works, which added greatly to his reputation. He was afterwards, for a number of years, engaged in laying out gardens in various parts of the kingdom, all of which showed considerable taste in design.

— **THE WEATHER.**—A change from a long period of mildness has occurred in the north. On Sunday night a storm is reported to have done considerable injury in some of the London market gardens. The temperature is now much lower, frost occurring on Tuesday morning, and snow falling freely in the afternoon in London.

— **MR. BLACKMORE'S PEARS.**—A fortnight ago we referred to this case of Pear stealing, in which a gardener pleaded guilty and was imprisoned, the greengrocer who received the fruit being remanded. He surrendered to his bail at the Middlesex sessions on Monday, and was sentenced to six weeks' imprisonment with hard labour.

— **GARDENING APPOINTMENT.**—Mr. H. Charles, late head gardener at Whitminster House, Stonehouse, Gloucester, has been appointed head gardener to Col. H. Davies Evans, of Highmead, Llanybyther, South Wales.

— **CYPRIPEDIUM SPICERIANUM.**—In our notice of this plant,

page 422, it should have been stated that all the plants at the Botanical Gardens, Birmingham, are growing in pans hanging from the roof, and in this manner the beauty of the flowers are best seen.

— A **LARGE CHESTNUT TREE.**—The following are the dimensions of a famous Chestnut tree growing in the pleasure grounds at Bestwood House, Stourbridge—namely, circumference 7 feet from the ground, 34 feet; spread of branches from north to south, 121 feet; from east to west, 100 feet.—F. ROBERTS.

— **THE** recent concert arranged by the members of the **CHISWICK GARDENERS' MUTUAL IMPROVEMENT ASSOCIATION** in aid of the Gardeners' Orphan Fund was held in the Vestry Hall, Turnham Green, and proved exceptionally successful, and resulted in a sum of £12 being presented to the Fund named. Mr. G. Gordon, the Chairman, took a prominent part in the preparation of the programme and the disposal of tickets, being assisted by several members, notably by Mr. J. Barry, who, having sold the requisite number of tickets, secures a life membership in the Orphan Fund.

— **THE** Scientific Committee of the Royal Horticultural Society have issued a series of questions on the subject of **THE EFFECTS OF LONDON FOGS ON CULTIVATED PLANTS**. In order to render the information as practical and as accurate as possible, it is desired that the experience of the current season only be utilised. Fresh specimens of plants showing injury caused by fog to either flowers or leaves may be sent for examination, accompanied by full particulars, to Dr. D. H. Scott, F.L.S., Normal School of Science, South Kensington, S.W., or to Dr. Francis Oliver, F.L.S., Royal Gardens, Kew. It is desired that the returns be made up to the end of March, 1890, and then returned to the Secretary, Royal Horticultural Society, 117, Victoria Street, S.W.

— **QUEEN WASPS.**—A correspondent recently remarked that his prediction as to the wasp abundance was fully realised during the past summer, and advised a sharp outlook for queen wasps this autumn. Since the appearance of the advice given I have found quite three dozen at different times concealed or that had intended to conceal themselves in spaces between the wall and windowframe of our fruit room. They evidently found their way through the stone roof, which is unsealed, as no other means were open to them whereby admittance could be gained. It would be interesting to know if your correspondent or other readers have secured any in a similar manner. The low buzzing sound produced from slow wing movement was the first indication for research.—W. STRUGNELL.

— **EUCHARIS DISEASE.**—My experience coincides with "M. D.," page 349, with reference to the Eucharis disease or mite. A few years ago I had charge of several fine healthy plants of Eucharis grandiflora in pots. Unfortunately the boiler, a plain saddle, was underneath the house, and a flue from the boiler the whole length of the house. One cold night in February the flue burst. The effect of the smoke and sulphur can be imagined. The Eucharis leaves laid over the pot sides as though affected by severe frost. After that for about two years they never seemed to do any good. The bulbs were repotted several times, always getting less in size until they were at last thrown away. I may mention that the Eucharis cannot bear strong sunshine. Give it all the light possible without the burning rays of the sun coming in contact with the leaves, which causes them to flag and the edges to turn brown. If the plants are overwatered when the sun is on them they will soon be out of health.—DIS.

— **PRUNING SHRUBS.**—Your correspondent "P." drew attention to this subject recently. My experience, though not so extensive, is of some years' standing. I think the best time to do this very necessary work is during August and September, especially where the object is to keep "shrubs within bounds." In pruning for this end, the long strong shoots have to be cut well back, leaving the more numerous but shorter shoots to form the plant. If this is done in November, these shorter shoots, from the fact that they have been surrounded and shaded by these stronger shoots, are not likely to be so well matured as those cut away, and therefore will be less prepared to stand a severe winter as they would be had the same thinning been done earlier. Another advantage is that it can be done with much more comfort, as it is not a very pleasant job getting amongst evergreens in the dull damp days of winter, when they are oftener wet than dry.—R. INGLIS.

— **BIRMINGHAM GARDENERS' MUTUAL IMPROVEMENT ASSOCIATION.**—The fortnightly meeting was held on November 12th, when Mr. J. Udale read an instructive paper on "Select Annuals for the Stove and Greenhouse," confining his list to twelve kinds only. These

were *Thunbergia alata* varieties, sown in shallow boxes in light soil, and transplanted into baskets or pots, recommending the adoption of the natural trailing habit of the plant to display its beauty, rather than the use of sticks. *Martynia fragrans*, sowing in succession from February to April in light soil, and covering the seeds with an inch in depth of soil, and place in a warm house. The varieties of *Celosia plumosa pyramidalis*, grown on in a compost of good loam, rotten cow manure, leaf soil, and sand. The varieties of *Torrenias* from seed, *Didiscus cœruleus*, *Browallia alata*, *Nicrenbergia gracilis*, *Balsams*, *Mignonette* of sorts, and *Zea japonica variegata*, for its bright variegation and ornamental character. In the discussion which followed a member asked Mr. Udale if he recommended the removal of the first blooms of *Balsams*, a plan adopted by many, and a reply in the negative was given. Mr. Hughes remarked that gardeners often experienced a difficulty in procuring seeds of a really good strain, and Mr. Spinks stated that in his experience of *Balsam* growing he had noticed that in order to make good pyramidal plants it was necessary to select seedlings which showed two growths or shoots. This Association has made great headway, and the library, now becoming an extensive one, is being considerably augmented. Mr. Hughes, the Secretary, announced as a present to the Association the gift from his employer of twelve volumes bound in half morocco of "Sowerby's British Botany," and "The Herefordshire Pomona," complete to date, the result of subscriptions collected by him for this purpose.

EUPATORIUMS.

It is surprising these are not given more prominence in advertisements and greenhouses at this season, and they are, in my opinion, the most easily managed and most floriferous of all white flowering plants from the beginning of October until January. They are evergreen, of a bushy habit, and they may be grown as specimens a foot high and the same in diameter in a 5-inch pot, or huge specimens from 1 to 2 yards in diameter may be produced in 10 or 12-inch pots, and in all cases they will be completely clothed with spreading heads of pure white flowers admirably adapted for vase decoration or furnishing crosses and wreaths. As I have hinted they flower for three or four months in succession, bear any amount of cutting, and require so little skill or attention, that the most inexperienced amateur would have no difficulty in securing abundance of flowers from them. They do not require to be forced to bring out the blooms, and they are perfectly at home in an unheated house or pit. They are easily propagated in spring, and they may be placed in the open air from June till September. A rich gritty soil suits them best, and they have the recommendation of being insect proof. I have grown them for many years, and they have never required cleaning, and they might be most profitably cultivated by all who desire to secure abundance of white flowers from early autumn until midwinter with trifling expense.—J. MUIR.

ALDIN GRANGE.

SOME time since an exceedingly agreeable day was spent in Durham and the gardens around that interesting old cathedral city, a journey undertaken in the company of an old friend, and with a genial and intelligent guide to show us what was worth seeing historically and horticulturally. An hour or two of a busily occupied day were spent at Aldin Grange, a few miles out from Durham, the residence of B. Cochrane, Esq. The garden is under the charge of Mr. W. Jenkins, who is known to many readers of this Journal by his practical contributions on various subjects, and enjoys somewhat more than a local reputation as a skilful gardener. The garden is not an extensive one, the glass accommodation is limited, and ornamental gardening is carried out on a moderate scale in such restricted space. Yet, as is often the case in small establishments, whatever is attempted is well grown, neatness and good culture prevailing throughout, and several useful lessons can be learnt by an inspection under the guidance of Mr. Jenkins.

Plants are not grown very largely, but amongst them are a few Orchids, of which *Dendrobiums* and *Phaius grandifolius* have been especially well cultivated. A group of these is represented in the woodcut (fig. 59, page 467), prepared from a photograph. These Orchids have not a structure specially devoted to them, but are grown in a mixed collection of stove plants, and are good examples of what can be effected in this way. There are some Orchids that succeed quite as well in an ordinary stove, provided they receive good attention, as if a house were devoted to them exclusively. One point, however, with regard to the *Phaius* should be mentioned—namely, Mr. Jenkins has found that it is easy to injure the plants by excessive resting, though some have strongly recommended a drying off process.

The plant stove is a span-roof structure, erected by Messrs. Richardson & Co., Darlington, and contains a good selection of plants. *Eucharises* have been infested with mite, but seem to be slowly recovering with the assistance of an annual washing of the roots with clean water; the best, however, are a few odd and inferior bulbs which were not thought to be worth potting, but by way of experiment were planted in cocoa fibre in the centre bed, where there is a good supply of bottom

heat. At the present time these appear to have outgrown the disease, and more are to be planted in the same way. A neighbour of Mr. Jenkins has succeeded on the same lines, but on taking the bulbs up and potting them they became unhealthy again. The *Camellia* house contains three very large specimens planted out, which annually produce large numbers of blooms. *Richardias* in 11-inch pots in this house are exceptionally good, with strong spathes.

There are four vineries. The earliest is planted with *Black Hamburgs* and *Foster's Seedling*. These Vines have been growing for the past five years in a border 3 feet wide by 15 inches deep, and with judicious feeding and top-dressing have produced Grapes every year equal to those growing in much larger borders. There are two rows of 3-inch pipes running under this small border, and what may appear strange is that the Vines annually retain their leaves longer than those in other houses which are started later. The second early house contains all *Black Hamburgs*, and many first-prize bunches are annually cut. The Vines have been planted about twelve years, the border inside and out, which has plenty of water at all times, including a good soaking of liquid manure water in the autumn. So strong was this given upon one occasion a few years ago that the whole of the paint became tarnished with the ammonia from the liquid that the whole had to be painted, but no other harm followed—quite the reverse. Another house planted five years ago contains *Alnwick Seedling*, *Black Hamburg*, *Madresfield Court*, *Duke of Buccleuch*, *Foster's Seedling*, and *Buckland Sweetwater*, all of which have produced prize bunches. The late vinery is facing due east, and so not well calculated to finish off *Gros Colmans* and *Muscats*. Nevertheless, by starting it in the middle of February *Gros Colman* is ripened by November. From this house many first prize bunches of *Alicantes* have been cut, some of which we have seen and admired, approaching Mr. Goodacre's celebrated bunch, about which the discussion arose, and which was figured in *Journal* some time ago. Nearly as fine samples were shown at York last week, and gained Mr. Jenkins the first prize in the class.

There are two ranges of Peach houses, the first in three divisions, planted with *Alexander*, *Hale's Early*, *Early York*, *Royal George*, and *Princess of Wales*, which ripen in the order named. The first-named is inclined to be over-vigorous, but is considered the best early Peach, being good in all points. *Hale's*, too, is an admirable Peach, closely following *Alexander*. *Princess of Wales* is, like many other showy kinds of fruit, not of the best flavour. One compartment in this range is chiefly devoted to *Nectarines*, *Hunt's Tawny* and *Stanwick Elruge* being the varieties grown, the former always colouring well, and carrying heavy crops annually. Another range in two divisions has recently undergone an alteration. The trees some twelve or fourteen years ago were planted against the back wall, but were not satisfactory; the houses have now been made suitable, and the trees planted in the front and trained under the roof in the usual way with the most gratifying results, so far as present appearances go. The varieties of Peaches are *A Bec*, *Bellegarde*, *Barrington*, *Royal George*, *Walburton* and *Late Admirable*; and the *Nectarines* *Victoria*, *Hardwicke*, and *Pitmaston Orange*.

In the Melon houses early crops of Tomatoes are grown front and back, at the back single plants in 11-inch pots are employed, *Dedham Favourite* being preferred to all others, while for a yellow *Harefield Grove* is grown. Melons follow the early Tomatoes, and a continual steady supply is secured from *Blenheim Orange* and *Best of All*. In one of these houses there is a large number of *Amaryllis* *aulica*, which commences throwing up its spikes in October and November, and the bright scarlet flowers are most useful during the winter. Some of these bulbs measure 17 inches round at the base, and most of them produce two spikes a year. The other section (spring flowering) is also represented, and although not consisting of the best modern varieties, there is a good collection. A large bulb of a variety named *Amazon* in the spring of last year produced five spikes, each containing four blooms, another four ditto, five bulbs producing an aggregate of seventy-five blooms. Yet the mite has been found in large numbers in this collection, many of the bulbs having decayed while growing side by side with these, and receiving the same treatment.

In addition to the walled-in kitchen garden of three-quarters of an acre, a piece about two acres has been fenced off by wire. Here the usual kinds of vegetables and Strawberries are grown. This land has been "farmed out," and was very poor, but with deeper cultivation and plenty of manure, chemical and otherwise, is being made to produce heavy crops. Strawberries are rather largely grown, over 2 cwt. having been used for preserving purposes this year, *Garibaldi* and *President* being mostly relied upon, although about ten other varieties are being tried, including *Noble*, *A. F. Barron*, *Burghley*, *President*, and others. A piece of ground is specially prepared, and good plants layered into 3-inch pots from plants put out the year previously, and a new plantation is made early in August. The plants stand for three years and are then dug up.—L. CASTLE.

CHRYSANthemum SHOWS.

ASCOT, SUNNINGHILL, AND DISTRICT.—NOVEMBER 12TH AND 13TH.

THIS Society held its sixth annual Exhibition of Chrysanthemums, fruit, and vegetables in the Grand Stand on the above date, but there were many blank spaces in the plant classes. Still, if the Show lacked quantity, the quality of the exhibits was fully up to the Ascot standard, which has always been high. Four competitors entered for the groups of Chrysanthemums to occupy a space 6 feet in radius Mr. Cowie,

gardener to Mr. Simms, Sunninghill, was first with a grand group, the plants well clothed with green healthy foliage, and carrying many fine blooms. Mr. W. Lane, gardener to Miss J. D. Smith, Ascot, was a close second; Mr. Hughes, gardener to H. F. de Paravicini, Esq., Heathfield, Ascot, third; and Mr. Hawthorne, gardener to Rev. B. K. Pearse, fourth. In the cut flower class centred in the competition for the challenge cup, to be won three times, with eighteen incurved and the like number of Japanese. Since it was offered in 1885 it has changed hands every year. This season it has been won by Mr. C. Page, gardener to H. P. Leschallas, Esq., Highams, Bagshot, the winner in 1887. The incurved blooms in the winning stand were clean, even, and very fresh. They were arranged as follows:—Back row: Emily Dale, Queen of England, Lord Alcester, Alfred Salter, Empress of India, and Golden Empress. Second row: Lord Wolseley, Princess of Wales, Violet Tomlin, Mr. Brunlees, Prince Alfred, and Mrs. Heale. Front row: Isabella Bott, Miss M. A. Haggas, Barbara, Lady Carey, Princess Beatrice, and Mabel Ward. The Japanese were large, bright, and fresh, being arranged as follows:—Back row: Stanstead White (this bloom received the National Society's certificate as the best Japanese in the Show), E. Molyneux, Etoile de Lyon, Madame J. Laing, George Daniels, and Triomphe de la rue des Châlets. Second row: Madame C. Audiguier, Sunflower, Mdle. B. Pigny, Ralph Brocklebank, Sarah Owen, and Mr. H. Cannell. Front row: Thunberg, Mrs. W. A. Harris, Balmoreau, J. Délaux, Avalanche, and Madame Baco. Mr. Lane, gardener to Miss J. H. Smith, last year's winner, was a very close second; his back row incurved flowers was heavy, and contained a grand Lord Alcester, which gained the National Society's certificate as the best incurved bloom. Mr. Hughes was a good third. In the class for eighteen incurved, open to all, Mr. Page was again first with a fresh even lot; Mr. Hughes was second; Mr. Cole, gardener to — Hamilton, Esq., Charteries, Sunningdale, third.

For the best eighteen reflexed, distinct varieties, Lady Isabella Keen offered a silver cup to be won twice in succession. Mr. Cole was first with a heavy stand of flowers; Mr. C. Page was second; Mr. Tomlin, gardener to T. Ashby, Esq., Sunninghill, third. Eighteen Japanese, distinct, brought nine entries, and Mr. C. Page won with fine heavy flowers; second, Mr. Thorne, gardener to J. T. Mackenzie, Esq., Sunninghill; third, Mr. W. Lane. The smaller classes were well filled, the prizes for twelve incurved going to Mr. Bullimore, gardener to A. Southard, Esq., Fern Lodge, Bracknell; second, Mr. Poppel, gardener to the Hon. Lady Stepney, Ascot; third, Mr. H. Godfrey, gardener to Mr. Rothery Ribsdon, Windlesham, Surrey. The corresponding class for Japanese to Messrs. Bullimore, Godfrey, and Tomlin in the order named. For six incurved, one variety, Mr. Godfrey won with good Empress of India, Mr. Hughes second, Mr. W. Lane third. Six Japanese, one variety, Mr. Page won with Triomphe de la rue des Châlets, grandly coloured, and of large size; Mr. Woodhouse, gardener to Miss Belcher, Sunningdale, second; Mr. Thorne third. Table plants, Cyclamens, and Primulas were well shown. Messrs. Sutton & Sons offered prizes for six dishes of vegetables, these going to Messrs. Poppel, Page, Hughes, and Worsfold in the order named. Messrs. Standish, Royal Nurseries, Ascot, had a large and beautiful group of Heaths, Palms, Chrysanthemums, &c., tastefully arranged. The Society have great cause to be thankful to Mr. J. Hay, gardener to Sir Arthur Hayter, South Hill Park, Bracknell, who carried out his duties with energy and tact.

TORQUAY.—Nov. 13TH.

THE most successful Chrysanthemum Show ever held at Torquay took place under the auspices of the Torquay Horticultural Society on the above date. The arrangements throughout were perfect, and the receipts nearly double those of any previous one. Of cut blooms there were about seventy stands in all, the premier prize being a silver cup value £5 5s. for eighteen incurved and eighteen Japanese, distinct. This was won by Mr. W. Dolling, gardener to Mrs. Wild, White Hill, Newton Abbot, whose incurved were, throughout the Show, extraordinarily heavy and fresh, though a trifle rough. His Japanese were small but fresh. The second prize of £3 3s. was won by Mr. Barnes, gardener to T. C. Daniel, Esq., Stoodleigh Court, Tiverton. In this stand, which was only just beaten for the cup, the Japanese were far superior to those in the first prize stand, but the incurved, though well finished, were small. Mr. Hobbs, gardener to Captain Philpotts, R.N., Chelston Cross, Torquay, took third prize, staging finer Japanese than the cup lot, but inferior to those in the second prize stand. His incurved were not strong. For twelve incurved, distinct, the first prize was taken by Mrs. Wild's gardener with heavy and fresh blooms, and the second by Mr. A. Serle, gardener to J. N. Whitehead, Esq., Gnaton, Torquay, with well finished small flowers, but rather past their best. With twelve Japanese, distinct, the first place was just won by Mr. Barnes, through one or two in the stand exhibited by Mr. Whitehead's gardener being past their best. Both stands contained excellent blooms. For six reflexed, distinct, Mr. Searle took the first prize, the other two exhibitors being disqualified for including Amy Furze; and with six Anemone flowered, distinct, Mr. Serle again won. For six reflexed, one variety, all three exhibitors showed Cullingfordi, Messrs. Dolling and Hobbs taking first and second prizes respectively from Mr. Serle with fresher blooms, though the latter's were much the deepest and largest. For six Anemones, one variety, the gardener to Miss Fripp, The Grove, Teignmouth, was first with a lovely stand of Fleur de Marie, Mr. Dolling being second. The difficult class of twelve blooms, one variety, brought a beautiful stand of Mdle. Lacroix to the front, exhibited by Mr. Whitehead's gardener, Miss Fripp's gardener being second with a fair stand of Meg Merrilies.

Six new varieties saw Messrs. Curtis & Sanford ahead, Messrs. Dolling and Searle following in the order named. For six single, Mr. Searle won with fine examples of Admiral Sir Thomas Symonds. In the amateur classes, which at Torquay are open to all except nurserymen, the competition was keen.

Groups were excellent, and in the first prize one, circumference 24 feet, exhibited by Mr. Whitehead's gardener, there was scarcely a bloom that would have been out of place on the show board. Other prizes in groups and plants were won by the gardeners of Captain Lane Tucker, J. N. Whitehead, Esq., Captain Philpotts, R.N., Lady Macgregor, J. W. Kimber, Esq., and A. Matthews, Esq.

GODALMING AND DISTRICT.

THE sixth annual Show of this Society was held in the Public Hall on the 13th and 14th inst., the specimen plants and cut blooms being of a very high order. In the class for six dwarf-trained plants, for a silver cup given by the tradesmen of Godalming, Mr. T. H. Cubbon, gardener to G. H. Pinkard, Esq., J.P., Combe Court, led with grand plants from 5 to 6 feet through, carrying over a hundred fine flowers. Mr. G. Edwards, gardener to the Dowager Countess Enniskillen, was a very close second. For one incurved specimen Mr. Edwards was first, and for one Japanese Mr. Cubbon was first. For the best group as grown staged for quality and effect Mr. Edwards won, Mr. Cubbon again following. For three trained Pompons Mr. Cubbon was first, and for single ditto Mr. Edwards first. For three plants in pots not disbudded Mr. R. Jordan, gardener to Miss Hallam, was first; Mr. King, gardener to — Cooper, Esq., second; Mr. F. Jordan, gardener to Birkett Foster, Esq., Witley, third. For a group of miscellaneous plants Mr. W. Wiles, gardener to C. Phillips, Esq., Unstead Park, was first.

The classes for cut blooms were keenly contested. For thirty-six—twelve Japanese, twelve incurved, and twelve Anemones—Mr. T. H. Cubbon took the lead, his chief blooms being Lord Alcester, Empress of India, Miss M. A. Haggas, Violet Tomlin, Princess of Wales, E. Molyneux, Condor, Madame Baco, Lady Margaret, and Annie Lowe; second Mr. Dodman, gardener to E. Evans, Esq., Witley; third Mr. G. Edwards. Mr. Edwards won with eighteen incurved, and with six incurved Mr. Nash, gardener to J. C. Ramsden, Esq., C.C., was first. For eighteen Japanese, distinct, Mr. Edwards was again to the fore with some grand blooms; second Mr. Dodman, third Mr. Cubbon, fourth Mr. Nash. Mr. Paddon, gardener to P. Ricardo, Esq., Bramley, won with twelve, Mr. R. Jordan being second, the latter winning with six. For twelve incurved first Mr. Dodman, second Mr. Paddon, third Mr. F. Jordan. For six Japanese, one variety, Mr. Edwards led with M. J. M. Pigny; second Mr. R. Jordan, with Avalanche; third Mr. Dodman, with Ralph Brocklebank. For six incurved, one variety, Mr. T. H. Cubbon was first with fine blooms of Lord Alcester; Mr. Edwards second with Golden Empress; and Mr. Dodman third. For twelve Anemone-flowered first Mr. Dodman, second Mr. Edwards, third Mr. Butcher, gardener to the Hon. Mrs. Joynes. Table plants were well shown.

With the exception of Grapes fruit was poorly shown, being very scarce in this neighbourhood. For six dishes, distinct, Mr. R. Jordan was first, Mr. G. Stening, Farncombe, being second. For six dishes of Apples, first Mr. R. Jordan, second Mr. T. Cubbon; ditto Pears, first Mr. W. Wiles, second Mr. R. Jordan. For two bunches of Muscats first Mr. R. Jordan, with fine bunches, good in berries and colour; second Mr. Bond. Ditto black, first Mr. Dodman, with fine sample of Alicante; second Mr. R. Jordan, third Mr. Bond. The exhibits of amateurs and cottagers showed a marked improvement on former years.

NOTTINGHAM.—NOVEMBER 13TH AND 14TH.

THE annual Show of Chrysanthemums and Fruit in connection with the Notts Horticultural and Botanical Society was held in the Arboretum Rooms on the dates named, when there was a brilliant display of the favourite autumnal flower; in fact, the most varied and excellent in quality that the members of the Society have yet produced. The specimens produced a most gorgeous effect. The groups as usual were the principal features and attracted a large share of attention. On Wednesday evening the Show was open to subscribers only, the general public having access on Thursday. Financially the Show was the most successful one the Society has yet held, and the able and efficient manner in which Mr. Edward Steward, the Secretary, carried out its arrangement is worthy of example.

The first prize for Chrysanthemums grouped with other foliage plants was awarded to the President of the Society, W. H. Farmer, Esq., for a somewhat heavy but otherwise very effective arrangement; J. Robinson, Esq., Nottingham (gardener, Mr. Plumb) being a close second with a bright and evenly balanced arrangement, but deficient in the main feature, a want of flowering Chrysanthemums. C. J. Cox, Esq., Rock House, Basford (gardener, Mr. Meadows) was a good third. So good were the groups that the Judges awarded an extra prize to James Booth, Esq. (gardener, Mr. Ralph). In the class for groups of plants arranged for effect in a space of 10 feet by 10 there was again keen competition, R. Halford, Esq., Nottingham (gardener, Mr. Taylor), securing chief honours with a very light arrangement, Cecos Weddelliana forming the centre and corners, with a groundwork of common wood moss. Mr. C. J. Cox came second with a pretty little group, and Mr. W. H. Farmer third.

In the class for twelve cut blooms (Japanese) P. L. Mills, Esq., Ruddington Hall, Nottingham (gardener, Mr. Hesford), obtained first place with really grand examples of Sunflower, Madame Audiguier,

Marguerite Marrouch, E. Molyneux, Moonlight, Baronne de Prailly, Belle Paule, J. Délaux, Madame Payne, Mr. Hillier, Val d'Andorre, and Avalanche. H. J. Pollock, Esq., Southwell (gardener, Mr. G. Dyke) was a good second, and Mr. C. J. Cox obtaining third. For six Japanese Mr. P. L. Mills was again first, Mr. C. J. Cox second, and Mr. G. Harriman, Lenton, Notts, third. In the class for twelve incurved varieties Mr. C. J. Cox obtained first, Queen of England, Lady Slade, and White Beverley being his best flowers. The same exhibitor was first for six blooms, Messrs. T. B. Hallam, Nottingham and Mr. A. Clark, Nottingham, being second and third respectively. In the classes for reflexed and Pompons only poor examples were staged, Mr. E. Massey, Nottingham, and Mr. J. Booth being the principal prizewinners.

In the class for six Chrysanthemum plants the competition was good, J. Hallam, Esq., Sherwood Rise, Nottingham (gardener, Mr. Newton), was first with well grown specimens, Mr. E. Massey and Mr. J. Robinson following. For three Chrysanthemum plants Messrs. J. Booth and J. W. Turner, Esq., Nottingham, obtained the chief places. Other classes for plants were fairly represented.

FRUIT.—The various classes for fruit were well filled. Prizes for Grapes were won by H. R. Clifton, Esq., Clifton Hall, Nottingham (gardener, Mr. Anderson); H. J. Pollock, Esq.; J. Hardy Carter, Esq., Sherwood; Mrs. Lennon, Sherwood. For dessert Apples by Mr. Clifton. For six varieties of dessert Pears by Mr. T. Bateman; Mr. J. W. Turner and Mr. T. B. Hallam third. For cooking Apples Mr. R. Halford, Mr. H. F. Pollock, and Mr. H. R. Clifton. The entries in the various classes for single dishes were very numerous and comprised splendid fruits of all the popular varieties.

Amongst those who exhibited fruit and vegetables not for competition were Messrs. Barber & Son, Nottingham; Messrs. Skinner and Rook, Nottingham; Messrs. J. R. Pearson & Sons, Chilwell; Messrs. Merryweather, Southwell; H. Frettingham, Beeston; Mr. J. Baker, Basford; Mr. W. Johnson, Arlockton, and Dr. Powell of the Coppice Asylum, Nottingham, the latter being awarded a special prize for a large and varied collection of vegetables.—J. H. W.

WALTON AND HERSHAM.

THE fifteenth annual Show of this flourishing Society was held in the new village hall, Hershams, on the 14th inst., and proved a success in every way. Her Grace the Duchess of Wellington kindly consented to open the Exhibition, and in a few well-chosen words Captain Terry, the Hon. Treasurer, said that financially the Society was in a better condition than had been the case for some years, and he hoped the Show would be held every third year at Hershams. The exhibits were more numerous than ever and of uniform good quality throughout. Mr. Masters, the Secretary, ably assisted by the Committee, arranged all the plants and blooms in a very pleasing way and everything passed off most agreeably.

Prize List.—Six plants dwarf trained. First, Mr. Reed, gardener to E. Pettit, Esq., Oatlands Park; second, Mr. Millican, gardener to H. Cobbett, Esq., Walton. Three plants.—First, Mr. Cawte, gardener to Preston Thomas, Esq., Weybridge; second, Mr. Felgate, gardener to Her Grace the Duchess of Wellington; third, Mr. Gardener, gardener to R. H. Turner, Esq., Walton. Standards were well represented, both large flowering and Pompons, by Messrs. Millican, Reed, and Gardener; and pyramids were beautifully shown by Messrs. Millican and Reed. Mr. Reed was placed first for four dwarf-trained Pompons, but some preferred Mr. Williams's second-prize plants, they being far fresher, although a trifle smaller.

Cut blooms, open class, twenty-four incurved and Japanese, twelve varieties of each. First, Mr. Carpenter, gardener to Major Collis Brown, Byfleet, with a splendid stand, the varieties being as follows, named as arranged:—Incurved.—Lord Alcester, Empress of India, Queen of England, Golden Empress, Princess of Wales, Alfred Salter, Golden Queen, Barbara, Nil Desperandum, Refulgens, Mabel Ward, and Mr. Brunlees. Japanese.—Duchess of Albany, Avalanche, Mr. Cannell, Boule d'Or, Fair Maid of Guernsey, Criterion, Madame J. Laing, Mdle. Lacroix, Sarah Owen, Stanstead White, Thunberg, and Madame Baco. Second, Mrs. Thorne, gardener to A. E. Flood, Esq., Walton, with a very beautiful stand, but not quite so heavy as the first. Third, Mr. Reeves, gardener to General Annesley, Oatlands Park, with a moderate collection. Twenty-four incurved.—First, Mr. Thorne, with a very even stand; second, Mr. Quarterman, gardener to C. E. Smith, Esq., Cobham; third, Mr. Millican. Twenty-four Japanese.—Mr. Quarterman was first with a very heavy stand; second, Mr. Thorne; third, Mr. Millican. Twelve incurved.—First, F. Hopkins, gardener to J. Widderspoon, Esq., Walton; second, Mr. Doyle, gardener to E. B. Alyward, Esq., Hershams; third, Mr. Felgate. Twelve Japanese.—First, F. Hopkins; second, Mr. Felgate; third, Mr. Cawte. In the first-prize lot was a Belle Paule, which the Judges considered the best example they had seen this season. Six incurved, one variety.—First, Mr. Thorne, with Empress of India, excellent; second, Mr. Reed; third, Mr. Quarterman. Six Japanese, one variety.—This was a strong class, there being eight entries. First, F. Hopkins, with Thunberg of a better colour than usually seen; second, Mr. Felgate; third, Mr. Thorne, with Stanstead White, which some thought better than Mr. Felgate's Boule d'Or. All the minor classes were well filled, and we were pleased to see amateurs and cottagers in stronger force than usual, and with very creditable produce.—F. H. W.

LINDFIELD.

THE fifth annual Show was held on November 14th and 15th. A fine display of groups, plants, and blooms was staged, and it was

generally admitted to be the most successful Show yet held. The classes for cut blooms were well contested, Mr. T. Venn, gardener to W. Studry, Esq., Paxhill, was first for eighteen incurved, staging Lord Alcester, Empress of India, Golden Empress, Queen of England, Barbara, Empress Eugénie, Lady Hardinge, Jardin des Plantes, Mrs. Heale. For eighteen Japanese Mr. R. Gibbins, gardener at The Châlet, was first with grand blooms of Avalanche, J. M. Pigny, Madame Audiguier, M. Freeman, &c.; Mr. T. Venn being second. In the class for twelve Japanese Mr. J. Voss, gardener to W. Savill, Esq., The Finches, was awarded first prize for good blooms of Ralph Brocklebank, Meg Merillies, Gloriosum, Carew Underwood, Duchess of Albany, Japonais, Fair Maid of Guernsey, Moonlight, Comtesse de Beauregarde, J. Laing, Jeanne Délaux, and M. Astorg. Mr. R. Gibbins took premier position for twelve incurved, showing Lord Alcester, Guernsey Nugget, Lady Hardinge, Jeanne d'Arc, Queen of England, Jardin des Plantes, Empress of India, Golden Empress, Empress Eugénie, Mrs. Heale, &c. He was also first for twelve reflexed and Anemone-flowered, staging King of Crimson, Cloth of Gold, Golden Peach, and Pink Christine, Fleur de Marie, Empress (large), and Madame Cabrol. There were ten groups staged, five large and five smaller, Mr. J. Hodges, gardener to M. C. Gibbons, Esq., Great Walstead, being awarded first prize for an artistic group in the larger class, and C. Wheeler first in the amateur class. There was also a class for the six best plants, each carrying six blooms, two each of either Japanese, incurved, reflexed, or Anemone-flowered. Some good specimens and standards were also shown. The show of fruit and vegetables was particularly good, and elicited the warm commendation of the Judges—Messrs. W. Balchin of Hassocks, J. Bunny of Dunny Gardens, Hurstpierpoint; and J. Hopkins, Highercross, Framfield.

HIGHGATE—14TH AND 15TH NOVEMBER.

THE fifth Exhibition of the Highgate, Finchley, and Hornsey Chrysanthemum Society took place at the Northfield Hall on the above dates, and notwithstanding a very thick fog during the whole of the first day, proved to be a decided success in every particular. It was remarkable for a grand display of well grown specimen plants. A challenge vase, value 21 guineas, for two specimens, one incurved and one Japanese, already won twice by Mr. J. Brooks, gardener to W. Reynolds, Esq., The Grove, Highgate, was again won by the same exhibitor, and this being the third occasion of his winning it, the vase now becomes his absolute property, in accordance with an agreement made with the donor. The incurved variety, Mr. George Glenn, was a splendid plant, and the Japanese variety Wm. Robinson was having about 170 good blooms. In the class for six specimen plants, Mr. Brooks was again first with grand plants, and Mr. Brittain, gardener to F. Reckett, Esq., J.P., Caen Wood Towers, a good second, the third prize being taken by Mr. Grundy, gardener to Horace Regnart, Esq., Highgate Lodge. Several good groups were set up, the two best being made to occupy a space not exceeding 66 feet. In this Mr. Brooks was again first, being very closely followed by Mr. Brittain, whose group would have been better had more time been spent in finishing it off.

In the open class for thirty-six blooms, eighteen incurved and eighteen Japanese, distinct, there was unfortunately only one competitor, Mr. B. Calvert, gardener to J. A. Houlton, Esq., Bishops Stortford, who was placed first, and would have been difficult to beat in good competition. Numerous classes for cut blooms, open to members only, were offered, the principal classes being as follows:—With twenty-four Japanese blooms, not less than eighteen varieties, Mr. Brittain was an easy first, having good examples of Mr. Garnar, Florence Percy, Duchess of Albany, Ed. Audiguier, Meg Merillies, Ralph Brocklebank, and E. Molyneux; Mr. Brooks second, and Mr. McLean, gardener to G. Kent, Esq., Southwood, third. In the class for twelve Japanese, distinct, Mr. Brittain was again first, having fresh and good blooms, Mr. Bushby, gardener to S. C. Thomas, Esq., Woodlands, Muswell Hill, second, Maiden's Blush and H. Cannell being particularly good. For twenty-four incurved blooms, Mr. Brittain was again placed in the premier position, having good blooms of Empress of India, Lord Alcester, John Salter, Barbara, Alfred Salter, and Mrs. Shipman; Mr. McLean was second, and Mr. Aitken, gardener to Goodhall, Esq., Highgate Road, third. In the class for twelve incurved blooms, Mr. Bushby was first, Mr. McLean second, and Mr. Brittain third. A class for six incurved, one variety, brought some grand blooms of Lord Alcester from Mr. Brittain, who was also awarded a certificate, Mr. Bushby being second. Several classes, open to single-handed gardeners only, were very creditably filled, the chief prizewinners being Messrs. Caryer, Türk, and Neary.

The class of most interest in the amateurs' division was for twelve Japanese blooms, in which the competition was very keen, the first prize being finally awarded to Mr. T. Press (Secretary), Victoria Cottages, Archway Road, very closely followed by Mr. D. B. Crane, 4, Woodview Terrace, Archway Road, who was beaten by one point only, the third prize being taken by Mr. Sears of Hornsey. In a tent adjoining the hall were placed table decorations, bouquets, sprays, &c., and also the cottagers' exhibits. In the class for table decorations, open to all members, Mr. T. Türk was first, Mr. D. B. Crane second, and Mr. Wilkinson third. In the amateur class for the same Mr. Crane was first; Mr. Murrey, Northwood Road, second; and Mr. J. Smith, Fitzroy Park, third. There was a marked increase in the attendance on each day as compared with last year, and the Committee hope to report shortly a considerable balance in hand.

DERBY.—NOVEMBER 15TH.

THE fifth annual Exhibition of Chrysanthemums was held at the Drill Hall on the above date, and I am informed was a financial success. The Hall was crowded at the time of my visit on the evening of the 16th, and I am told 1000 persons paid for admission on the opening day. In the principal open class for twenty-four blooms, twelve incurved and twelve Japanese, Mr. Goodacre, gardener to Lord Harrington, Elvaston Castle was easily first with substantial blooms. In Japanese a fine example of Stanstead White was noticeable. The prize was a handsome Derby china vase, value £10 10s., and 40s. in cash. This had to be won

In the division 1, open to the United Kingdom, class 1, for twenty-four incurved varieties, distinct, Mr. Brown, gardener to R. Henty, Esq., Langley House, Abbots Langley, was an excellent first with very good blooms. Class 2, twenty-four Japanese varieties, distinct, Mr. George Sturman, Queen Street, Watford, was an excellent first with flowers far above the average; Mr. Brown being second, and Mr. Kirby, gardener to E. Mawley, Esq., Berkhamstead, third. Mr. King, gardener to W. McFarlane, Esq., Glenchess, Rickmansworth, showed a splendid twenty-four Japanese, not for competition. Class 3, open to members only, miscellaneous groups of plants not exceeding 50 feet.—Mr. Lowe, gardener to the Right Hon. The Earl of Brownlow, the President of the

FIG. 59.—A GROUP OF ORCHIDS AT ALDIN GRANGE. (See page 464).

twice consecutively or three times altogether. In the members' classes the principal prize is the challenge cup, value £5 5s., and 20s. in cash, was well won by Mr. F. Bancroft, an enthusiastic amateur. He had in his collection the premier bloom, a good example of Avalanche in fine condition. Messrs. Pearson of Chilwell staged some fine fruit and three trained specimens of Chrysanthemums, which were much admired. The Committee hope to produce a still better Show next year by offering more liberal prizes.—VISITOR.

BERKHAMSTEAD.—NOVEMBER 15TH.

THE second annual Exhibition of the above Society was held in the Town Hall, Berkhamstead, on the date named, and was very successful.

Society, was an excellent first; Mr. Hillier, gardener to H. H. Cooper, Esq., Berkhamstead, second; and Mr. Smyther, gardener to Colonel Barclay, was third. Class 4, for groups of Chrysanthemums in a space of 40 feet.—Mr. A. B. Higgins, gardener to A. G. Lucas, Esq., was first with very even blooms. He was also awarded Messrs. Wood & Son's medal for the most meritorious exhibit grown with their liquid manure powder. Mr. Higgins was first for three specimens Japanese, also for a single specimen. Mr. Kirby was first for twenty-four Japanese, and Mr. Hicks, gardener to J. G. Pearson, Esq., for twelve incurved blooms. For twelve Japanese Mr. Folkes first. Mr. Elser won both Messrs. Carter's and Messrs. Cutbush's prizes. There was a capital exhibit of Orchids by G. Alcock, Esq., for which he was very highly commended. Messrs.

Lane & Son staged forty-one dishes of Apples, not for competition. The annual dinner of the Society took place in the evening at the King's Arms Hotel, Mr. F. Lane in the chair. Mr. Lane said he had great pleasure in informing those present that Lord Rothschild had given a subscription of £3 to the funds of the Society.

ECCLES, PATRICROFT, PENDLETON, AND DISTRICT.

NOVEMBER 15TH AND 16TH.

THE third annual Exhibition of Chrysanthemums was held in the Town Hall, Eccles, and it was in every respect a complete success. The exhibits were of unusual quality both in the open and amateur classes. Chrysanthemums in pots were well represented. Four groups were staged, and Mr. T. Belshaw, gardener to G. H. Leigh, Esq., being successful with a group; Mr. H. J. Bennett, gardener to N. A. Earle, Esq., second; and Mr. John Leech, gardener to John Brennand, Esq., third. With specimen plants Messrs. N. A. Earle, M. J. Macdonald (gardener to Marcus S. Bles, Esq.), and J. Barlow were the most successful, Mr. Earle taking several firsts. In the amateur class Mr. Th. Marlow and Mr. James Smethurst won the first prizes. Cut blooms were very numerous and of first-class quality. In the open class for twenty-four blooms, twelve incurved and twelve Japanese, Mr. T. Walker was first with a stand of splendid large and well-grown blooms; Mr. T. Cragg, gardener to A. Heine, Esq., being a good second. For twelve incurved blooms Mr. A. Heine was first, and Mr. T. Walker second. For twelve Japanese blooms the first prize was awarded to Mr. T. Walker, and the second to Mr. S. Goodall, gardener to A. H. Sykes, Esq. For six incurved and six Japanese Mr. T. Walker was again first, and Mr. A. Heine second. In the class for twelve cut blooms—comprising incurved, Japanese, reflexed, and Anemone-centred—Mr. T. Walker was again first, and Mr. A. Heine second. Mr. T. Walker also won the first prize for six Anemone-centred blooms. In the amateur class for one collection of eighteen cut blooms, staged for effect, Mr. H. Huber carried off the first prize, and Mr. Wm. Crawshaw the second. For twelve blooms, six incurved and six Japanese, Mr. Crawshaw was first, and Mr. W. Eckersley second; and for twelve cut blooms—viz., three incurved, three Japanese, three reflexed, and three Anemone-centred—Mr. Crawshaw was first, and Mr. H. Huber second. There were several smaller classes. There were also classes for the members of the Patricroft Linnæan Society, Mr. Smethurst carrying off the first prize for twelve cut blooms, six incurved and six Japanese. For six incurved blooms Mr. R. Johnson took the lead; same exhibitor was first for six blooms—two incurved, two Japanese, and two Anemone-centred. For six Japanese blooms Mr. T. Royles was first.

One of the most tastefully arranged groups of miscellaneous plants arranged for effect was shown by Mr. W. Elkin, gardener to Mrs. Th. Agnew, for which he was awarded the first prize. The same exhibitor won the first prize for six table plants. Orchids and other plants, for mention of which space cannot be found, added to the attractiveness of the Exhibition. Messrs. W. Clibran & Son, Altrincham, staged a few dozen cut Chrysanthemum blooms. For two new varieties—Annie Clibran (a sport from *Mdlle. Lacroix*) and *L'Automne*—first-class certificates were awarded by the Judges. Messrs. Dickson & Robinson, Manchester, made a good display of small Palms, table plants, and flowering plants. Mr. T. Derbyshire of Patricroft contributed twenty-four plates of Apples grown in his orchard at Barton. An excellent orchestral band was in attendance.

CUCKFIELD.—NOVEMBER 19TH AND 20TH.

THIS Society had their third annual Show at the Talbot Assembly Rooms, Cuckfield, on the above dates, and the display of plants, flowers, fruit, and vegetables was quite up to those of former occasions. The result in the open class competition for cut blooms shows that the older sister Society at Lindfield still maintain their superiority, for while they carry off the honours at Cuckfield, none of the growers from the latter place have invaded Lindfield territory. Both societies are, however, in need of larger places to hold their shows in, for the crowds of visitors in the evenings are so tightly packed as to preclude comfortable inspection and to endanger the safety of the exhibits.

The small amount of prizes given for groups do not seem to deter local men from entering the list. Only six could be staged in the room, and each space was filled, and though they varied in size and quality of bloom and arrangement, it must be said that they were all composed of suitable and well-grown plants. The first prize was worthily awarded to Mr. R. Fairbairn, gardener to Mrs. Lister, The Grange, Warrington; the second to Mr. G. Stringer, gardener to R. A. Bevan, Esq., Horrogate, their chief superiority being in size of blooms and vigour of foliage. Mr. T. First, gardener to F. M. Horth, Esq., Henmead Hall, was third, and Mr. J. Mitchell, gardener to Mrs. Maberly Mytens, fourth. This exhibitor had certainly the neatest and best finished group, and if he could put more vigour into his plants, and still keep them as dwarfs, he might reasonably expect a higher place. Specimen plants were not numerous, but well flowered, the chief winners being Messrs. T. First, J. Mitchell, and T. Burtenshaw. Primulas, Cyclamens, and Solanums were well shown.

Cut Flowers.—The chief interest was centred in the open class for twelve Japanese and twelve incurved. There was a good entry for the former, but a limited number for the latter. The coveted honour for twelve Japanese was awarded to Mr. J. Voss, gardener to W. Savill Esq., Finches, Lindfield, with a fine stand. They were—Back row, Meg Merrilies, Japonais, Ralph Brocklebank, and Duchess of Albany; second row, Baronne de Prailly, *Gloriosum*, J. Laing, and Mrs. Cannell; front

row, M. Astorg, Carew Underwood, Ceres, and Comtesse de Beauregard. Mr. R. Gibbins, gardener to W. Sturdy, Esq., The Chalet, Lindfield, was a good second, and had *Avalanche*, *Gloriosum*, and M. Freeman in good form. Mr. R. Baker, gardener to S. McClement-Hill, Esq., Wykeham, Burgess Hill, was third. For twelve incurved Mr. Gibbins had an easy victory with good blooms of—Back row, *Princess Imperial*, *Empress Eugénie*, *Queen of England*, and *Golden Empress*; middle row, *Princess of Teck*, *Golden Queen of England*, *Jeanne d'Arc*, and *Lady Hardinge*; front row, *Nil Desperandum*, *Guernsey Nugget*, *Barbara*, and Mrs. N. Davis. Mr. J. Lingley was second, and Mr. J. Manton third. In the corresponding local classes, Mr. R. Inglis, gardener to T. T. Cunliffe Lister, Esq., Borde Hill, was first for both Japanese and incurved, and Mr. T. Martin, gardener to A. S. Bicknell, Esq., Staplefield, was first for twelve reflexed. There was a good show of fruit, the chief exhibitors being Messrs. T. First, G. Stringer, J. Mitchell, R. Fairbairn, J. Lingley, J. Harding, R. Inglis, and J. Umpleby, several of whom also showed fine dishes of fruit not for competition. There was a keen contest for a tray of vegetables. Mr. W. Manton was again to the fore in this class, closely followed by Messrs. J. Mitchell, G. Stringer, and T. Burtenshaw in the order named. Much interest is taken in the progress of the Society by Major Maberley, the President, and no little credit is due to Mr. J. Umpleby, Superintendent, and to Mr. J. Tugwell, Secretary, for the success of their arrangements.

WATFORD.—NOVEMBER 19TH AND 20TH.

THE fourth annual Show of the above Society, held in the Watford Agricultural Hall on the above date, proved a great success. Too much cannot be said in its praise. The groups were magnificent, and the cut blooms, especially the Japanese, very fine and fresh. To give a detailed account would require much space, the classes being numerous and the entries plentiful. When we say seventeen groups of Chrysanthemum plants, three of miscellaneous plants, and the same number of Pelargoniums were in competition, and eight others, some of large dimensions, non-competitive, the extent of the Exhibition may be imagined. The arrangement throughout was perfect, and viewed from the gallery had a grand effect.

Groups.—In the open class for a group of Chrysanthemums not exceeding 50 square feet, Mr. Deane, gardener to the Earl of Essex, Cassiobury, Watford, was a good first with a fresh lot of plants, well arranged, and carrying large flowers, the best group in the Show. Mr. Davis, gardener to E. A. Woolley, Esq., Abbots Langley, second. Mr. Cox, gardener to J. Trotter, Esq., Hertford, third. For a similar sized group, competition confined to members only, Mr. Ashdown, gardener to C. R. Humbert, Esq., Watford, first. Second, Mr. Wilson, gardener to G. Rooper, Esq., Nascott House, among several competitors. For miscellaneous plants Mr. Brown, gardener to Lord Esher, Heath Farm, Watford, secured the first position with a nicely arranged group, consisting of Palms, highly coloured Crotons and *Dracænas*, flowering plants, groundwork of *Adiantums*. Second, Mr. Seabright, Stanmore; third, Mr. Condie.

Specimen plants made a good display. For three incurved Mr. Beckett was first with large plants of Mrs. Dixon, Lord Wolseley, and Mrs. G. Rundle. Second, Mr. Wilson; third, Mr. Layzell, gardener to the Rev. K. F. Gibbs. Mr. Beckett was the only exhibitor of three Japanese, having beautiful plants of *Henri Jacotot*, *Mdlle. Lacroix*, and *Wm. Robinson*.

Cut blooms, open classes.—Much interest was evinced here, especially in the Japanese classes, where the competition was generally keener than with the incurved flowers. For twenty-four Japanese, distinct, Mr. Beckett was well first, having blooms of great depth and breadth, completely covering the stands. They comprised—Back row: *Etoile de Lyon*, *Jeanne Delaux*, *Boule d'Or*, *Lady Lawrence* (very good), *Baronne de Prailly*, *Sunflower*, *E. Molyneux*, *Stanstead White*; middle row: *Gloriosum*, *Volunteer* (very pretty), *Madame Baco*, *Le Sceptre Toulouse*, *Ralph Brocklebank*, *Madame C. Audiguier*, *Avalanche*, *Carew Underwood*; front row: *H. Elliott*, *Thunberg*, *M. Brunet*, *Pelican*, *Marsa Japonais*, *Mrs. Mahood*, and *Marguerite Marrouch*. Second, Mr. Cox; Mr. G. Sturman, a Watford amateur, being a good third. Mr. Beckett was also the most successful competitor for twenty-four incurved, distinct, having good flowers of *Queen of England*, *John Salter*, *Golden Empress*, *Prince Alfred*, *Alfred Salter*, *Lord Alcester*, *Violet Tomlin*, *Empress of India*, back row; *Charles Gibson*, *Princess Teck*, *Mr. Brunlees*, *Beauty*, *Mrs. W. Shipman*, *Hero of S. Newington*, *Princess of Wales*, *Jardin des Plantes*, middle row; *Lord Wolseley*, *Refulgens*, *Angolina*, *Mrs. N. Davis*, *Lady Hardinge*, *Miss M. Haggas*, *Barbara*, and *Mrs. Hcale*, front row. Second, Mr. Brown, gardener to R. Henty Esq., Abbots Langley. Twelve Japanese.—First, Mr. Deane, having among others very fine blooms of *G. Daniels*, *Mr. H. Cannell*, and *Lady Lawrence*. Second, Mr. Tidy, gardener to W. D'Arcy, Esq., Stanmore, the latter being first for twelve incurved, and Mr. Rumbold, gardener to G. Lake, Esq., second. The six Japanese, one variety class, was strongly contested, Mr. Deane coming first with wonderful flowers of *Etoile de Lyon* of immense size, fresh, and of a deep purplish pink colour. Second, Mr. Beckett, also with beautiful flowers of *Lady Lawrence*.

In the second division, open only to members of the Society, Mr. Beckett was again successful in securing the first prizes for twenty-four incurved, and also for the same number of Japanese, the flowers being very similar to those mentioned in the open classes. Among the latter the new variety *Volunteer* was again staged; the colour is a pleasing peach pink and quite distinct, with florets of the *Belle Paule* type. Mr. Rumbold was second in Japanese, and Mr. Brown, Abbots Langley, for

incurred. For twelve incurred, Mr. Mundell, gardener to Lord Ebury, Moor Park, was first, having, among others, good flowers of Violet Tomlin and Princess Teck. Some good stands of reflexed blooms were staged by Mr. Brown and Mr. Mundell, who took the prizes in that order, and Pompons and Anemone Pompons were well shown by several exhibitors. In many other classes amateurs and single-handed gardeners exhibited strongly, the principal prizewinners being Messrs. Lansley, Sturman, Vincent, Chipps, Camfield, Smith and Browton.

Fruit and vegetables, especially the latter, were staged in large quantities, the quality being excellent, and filled one side of the large gallery. In the open class for twelve kinds Mr. Beckett added another to his many successes. Mr. Brown second. Many other classes were devoted to vegetables, the prizes offered by Messrs. Sutton & Sons, G. P. Darby, and several others. Messrs. Wattam, Beckett, Brown, and Anning won the chief prizes in the Grape classes. Table decorations, bouquets, &c., also formed an interesting feature in the Show.

Not for Competition.—The chief attraction was a large group of Chrysanthemums and miscellaneous plants arranged in the centre of the hall by Mr. Myers, gardener to the Earl of Clarendon, President of the Society. The tall Palms were an agreeable relief to the different groups of colour surrounding, and was altogether an admirably arranged group of excellent plants. Mr. Smith, gardener to E. H. Lloyd, Esq., Langleybury, also puts up an effective group, on which Orchids and Chrysanthemums figured largely. Collections of plants were also contributed by Messrs. Cutbush & Son, Messrs. G. P. Darby, Nicholson, Pinkerton, and some others. Messrs. Lane & Son, Berkhamstead, staged a collection of Apples, among which were some highly coloured and fine examples.

LIVERPOOL.—NOV. 19TH AND 20TH.

THIS Exhibition was a great success. The incurred blooms of Chrysanthemums were very little in advance of those last year, but the Japanese were fresh, large, and superior.

Cut Blooms.—In the open class for forty-eight blooms, twenty-four Japanese and twenty-four incurred, six collections were staged. Mr. R. Foster, gardener to S. H. Thompson, Esq., Thingwall Hall, Broadgreen, was deservedly placed first. The following comprised the varieties:—Japanese, back row: Boule d'Or, Sarah Owen, E. Molyneux, R. Brocklebank, M. Marrouch, Meg Merrilies, M. Bernard, and Boule d'Or. Second row: Madame Audiguier, Madame J. M. Pigny, Madame Baco, Mdle. Lacroix, M. Brunet, Pelican, and M. J. Laing. Front row: Avalanche (very good), M. Bernard, R. Brocklebank, Jeanne Délaux, Meg Merrilies, Belle Paule, Criterion, and Avalanche. Incurred, back row: Lord Alcester (2), Emily Dale (2), Empress of India (2), Queen of England, and Golden Empress. Second row: Queen of England, Golden Empress, Princess of Wales, Mrs. Shipman, Mrs. Heale, Alfred Salter, Princess Teck, and Jeanne d'Arc. Front row: Mrs. Norman Davis, Princess Teck, Barbara, Jardin des Plantes, Charles Gibson, Miss Haggas, Cherub, Hero of Stoke Newington. Second, Mr. John Edwards, gardener to H. Tate, Esq., Allerton Beeches, with fresh good blooms, the Japanese particularly fine. Third, Mr. A. R. Cox, gardener to W. H. Watts, Esq., Elm Hall, Wavertree. For eighteen blooms, incurred, Mr. Geo. Eaton, gardener to W. H. Shirley, Esq., Allerton House, was placed first with bright examples. Back row: Emily Dale, Princess of Wales, Miss M. A. Haggas, Princess of Teck, Jardin des Plantes, and Queen of England. Middle row: John Salter, Mrs. Heale, Hero of Stoke Newington, Cherub, Empress Eugénie, and Golden Empress of India. Front row: Lady Hardinge, Mr. Bunn, Nil Desperandum, Mr. Cullingford, Barbara, and Lady Carey. Second, Mr. J. Jellico, gardener to F. H. Gossage, Esq., Camp Hill, Woolton. Third, Mr. Thos. Foster, gardener to J. Brancker, Esq. Four collections were staged. With twelve blooms Mr. W. Wilson, gardener to H. Cunningham, Esq., Gorsey Cop, Gateacre, took the lead, followed by Mr. J. Brantingham, gardener to W. Radcliffe, Esq., Aigburth, and Mr. J. Warrington, gardener to T. Bright, Esq., Brierley, Aigburth. Five collections were staged. In the corresponding class for twelve Mr. J. Hathaway, gardener to the Earl of Latham, Latham House, Ormskirk, took the lead, followed by Mr. G. Buttler, gardener to J. Drysdale, Esq., Mossley Hill, and Mr. G. Lyon, gardener to J. H. Kenion, Esq., Rock Ferry, in the order named. Three stands were staged. For eighteen Japanese, six or seven were in competition. Mr. John Gould, gardener to R. N. Dale, Esq., Bromborough Hall, Birkenhead, was successful. Mr. J. Brantingham was placed second, and Mr. Thos. Foster third. Of twelve blooms seven or eight boxes were staged. Mr. J. Jellico was placed first with large fresh blooms. Second, Mr. J. Brantingham, and third Mr. Thos. Foster. In the corresponding class for twelve Mr. G. Butler took the lead, followed by Mr. Hathaway and Mr. A. R. Cox. For six Anemone flowered Mr. W. Wilson took the lead with large fresh flowers, and he also won with six reflexed. For twelve Pompons Mr. D. McKellar, gardener to A. J. Steel, Esq., Bank Hill Road, Aigburth, took the lead with capital flowers.

Chrysanthemums in Pots.—These were equal to the average of past years, and the groups showed a marked improvement. For a group of plants, Mr. H. Stone, gardener to R. Bennett, Esq., Weston House, Halewood, was first with well bloomed plants. For six untrained plants, Mr. Thomas Gowen, Mossley Hill, was placed first; Mr. W. Quirk, second; and Mr. S. McKellar third. With four trained large flowering plants Mr. Jos. Harrison, gardener to W. G. Bateson, Esq., led, having fresh well-grown examples. Mr. J. Hughes was a good second, and Mr. J. Rose, gardener to G. H. Parker, Esq., third.

Stove and Greenhouse Plants.—These were fewer than usual, Mr. A.

R. Cox being placed first for six plants, Mr. Jellico second, and Mr. A. Lewis third. Ferns were equal in numbers and quality to what have been staged in past years. Mr. Thos. Gowan won, Mr. A. R. Cox being a good second. Orchids were not numerous, but in quality they were in advance of any staged during the past few years. For three plants, Mr. A. Smith, gardener to D. de Zharronda, Esq., was placed first with *Lycaste Skinneri alba*, three expanded flowers; *Vanda Sanderiana* one spike, and *Cymbidium Mastersi*. Mr. B. Cromwell was second. With one *Cypripedium* Mr. Healey, gardener to Col. Wilson, won, having a fine plant of *Spicerianum* with fifteen flowers. Roman Hyacinths were exceedingly well staged by Mr. J. Kelly, gardener to R. Singlehurst, Esq., Aigburth.

Fruit.—There was a great falling off in the collections and some of the Grape classes, while the hardy fruit was equal, if not superior, to that staged in previous years. In the class for six dishes there were only two entries. First, Mr. J. Bounds, gardener to A. L. Jones, Esq., Oaklands, Aigburth, Grapes poor, Pears and Apples good. Second, Mr. W. Hannagan, gardener to R. C. Naylor, Esq., Horton Hall. For two Pines Mr. W. Kipps, gardener to J. Crosfield, Esq., Walton Lea, Warrington, was deservedly placed first with splendid fruits of Smooth Cayenne. Of two bunches of black Grapes, Alicantes, there were five collections staged, Mr. J. Downham, gardener to E. H. Harrison, Esq., Eastham, winning with good bunches. Second, T. Ferguson, gardener to Mrs. Patterson, Rock Ferry. Third, Mr. R. Brownbill, gardener to G. Fowler, Esq., Ravenwood, Rock Ferry. With two bunches of any other variety of black Mr. T. Ferguson took the lead with good bunches of Gros Guillaume. For two bunches of Muscat of Alexandria Mr. G. Middleton, gardener to Richard Pilkington, Esq., Rainford Hall, St. Helens, was placed first with splendidly finished examples. Second, Mr. W. Speed, very good. Third, Mr. W. Oldham, gardener to J. Beecham, Esq., Huyton. Extra prize, Mr. W. T. Wyton, gardener to Major Bird, Crookhey Hall, Garstang. For two bunches any other white only two exhibits were staged, Mr. J. Downham being first with Trebbiano, large highly coloured bunches. Second, Mr. S. McMaster, gardener to Sir U. Kay Shuttleworth, Bart., M.P., Gawthorpe Hall, Padiham. In the class for four bunches of Grapes Mr. W. Oldham was first with Lady Downe's, Muscat of Alexandria, Alicante, and Golden Queen, good. Second, Mr. J. H. Goodacre, gardener to the Earl of Harrington, Elvaston Castle, Derby. Third, Mr. G. Middleton. Five lots were staged.

Pears were good. Five collections were staged for the prizes offered for six dishes, Mr. J. Goodacre taking the lead; second, Rev. L. Garnett, Christleton Rectory, Chester; third, Mr. H. Forder, gardener to Col. Cornwallis West, M.P. Of four dishes eight collections were staged, the prizewinners being Mr. R. Pennington, gardener to E. Banner, Esq., Blacklow House, Roby; Mr. O. Winkworth, gardener to R. Brocklebank, Esq., Childwall Hall; and Mr. J. Kelly, gardener to R. Singlehurst, Esq., Endfield House, Aigburth. Mr. Hannagan was first with one dish, showing Marie Louise; second, Rev. L. Garnett, with Doyenné du Comice; third, Mr. R. Foster, with Marie Louise. For one dish stewing Pears, Mr. M. Quick, gardener to W. Polter, Esq., Thingwall Hall, Birkenhead, was first with Black Worcester; Mr. J. Rimmer second, and Mr. H. Foster third.

Apples were good, and the prizes offered were in each class well contested for. In the class for six dishes seven collections were staged. Rev. L. Garnett took the lead with Blenheim Pippin, Winter Peach, Ribston Pippin, Golden Winter Pearmain, Cox's Orange Pippin, and Melon Apple, all very fine. Second, Mr. J. Davies, gardener to the Rev. H. C. Sturges, Bodenham, Leominster. Third, Mr. H. Forder. For three dishes Mr. R. Pilkington took the lead, followed by Mr. W. Hannagan and Mr. W. Quick in the order named. There was no name to the first exhibit of one dish, Mr. B. Cromwell, gardener to T. Sutton Tinnies, Esq., being second, and the Rev. L. Garnett third. For eight dishes culinary Apples Mr. J. Davies took the lead with splendid examples of Peasgood's Nonesuch, Stirling Castle, Golden Noble, Emperor Alexander, Blenheim Pippin, Winter Nonesuch, and Warner's King. Mr. John Hyde second, and Mr. J. Goodacre third. Seven collections were staged. For four dishes Mr. R. Pennington took the lead, followed by Messrs. Hannagan and J. Rimmer. Mr. W. Davies was first with one dish, showing Stirling Castle very large.

Miscellaneous exhibits were numerous. Messrs. R. P. Ker & Sons staged *Cyclamens* in their well-known style; the Liverpool Horticultural Co. a mixed collection of plants; Messrs. Dickson, Limited, Chester, a collection of Apples; Messrs. Turner Bros. a collection of wreaths and bouquets; Messrs. Fishlock Bros. a similar exhibit, some of the sprays being particularly handsome; Mr. J. V. Smith a seedling *Croton* named Mrs. Ussher; and Mr. J. Watkins, Pomona Nurseries, Hereford, a collection of Apples. For these certificates of merit were granted. The Exhibition was admirably arranged.

WINCHESTER.—NOVEMBER 19TH AND 20TH.

THIS Society held their seventh Exhibition on the above dates. Cut blooms formed the leading part of the Show, the leading class being that for forty-eight, twenty-four to be incurred or reflexed, and the same number Japanese. The first prize was well won by F. W. Flight, Esq., Twyford, Winchester (Mr. Neville, gardener) with a wonderfully fresh even lot of Japanese, but a few of his incurred lacked freshness. The varieties were:—Japanese: *Etoile de Lyon* (2), Mr. Ralph Brocklebank (2), Meg Merrilies (2), *Baronne de Prailly* (2), *Carew Underwood* (2), *Lady Lawrence* (2), Mr. H. Wellam, Mrs. Cannell, *Gloriosum*, *Golden Dragon*, *Avalanche*, *Criterion*, Mrs.

Wheeler, Mrs. J. Wright, E. Molyneux, Souvenir de Angélé Amiel, Comte de Germiny and Mr. Cannell. Incurred: Empress of India, Queen of England (2), Miss M. A. Haggas (2), Lord Alcester (2), Princess of Teck (2), grand; Golden Empress, Putney George, Lady Dorothy (2), good; Beauty (2), Peach Christine. Hero of Stoke Newington, Mr. Brunlees, Mrs. N. Davis, John Salter, Nonpareil, Cherub, and C. Gibson. Messrs. W. & G. Drover second with blooms as large, but lacked freshness all through.

Another important class was that for twenty-four blooms in eighteen varieties, the best coming from Sir H. Mildmay, Bart., Dogmersfield Park (gardener, Mr. G. Trinder), with heavy lot bright and fresh blooms; second, Mr. Wills. For twelve incurved, distinct, Messrs. W. & G. Drover secured the chief position with well-finished blooms; second, Mr. W. Neville. For twelve Japanese, distinct, Mr. W. Neville gained first honours with a bright, fresh, and well arranged stand, similar to his forty-eight lot, Messrs. W. & G. Drover being second. In the class for twelve Anemones, not less than eight varieties, Messrs. W. and G. Drover had a magnificent stand, the varieties being Souvenir de Lardenne (2), Mdle. Cabrol (2) good; Lady Margaret (2), Miss Annie Lowe, W. & G. Drover (2), Laing's Anemone, Marguerite Villageoise, and Nouvelle Alvéole. Mr. W. Neville second.

In the class for twelve reflexed Mr. Wills was first with medium sized blooms; second, Mr. Neville. Mr. Bushby, gardener to F. Willan, Esq., Hill Park, Bitterne, took first honours with six incurved and six Japanese, distinct, and also for twelve blooms, not less than eight varieties. In this stand a bloom of Mrs. H. Cannell was grand, measuring 10 inches in diameter. Pompons was best shown by Mr. Neville, having a new one called Bessie Flight, a sport from Madame Montels, which the Judges awarded a first-class certificate. Colour similar to Queen of Anemones.

The best group of plants was arranged by Mr. A. Prouting, gardener to Miss Butler, Winchester, and the best specimen plants, very good indeed, were exhibited by Mr. F. Wakeford, gardener to G. Harris, Esq., Aldermore, Shirley. We are pleased to hear that the Show was better attended than any others of recent years.

YORK.—NOVEMBER 20TH.

THE annual Exhibition of the ancient Society of York Florists was held in the Fine Art Exhibition Buildings, which is admirably adapted for the purpose, as an effective display of groups and plants was easily obtained, those of a miscellaneous character being arranged in circular form in the centre of the hall at wide distances apart, thus allowing ample space for promenading. The specimen plants of Chrysanthemums were placed in blocks on the floor of the hall, while many adorned the sides.

For a group of Chrysanthemums interspersed with foliage plants arranged for effect in a space of 120 square feet, a special prize—a silver cup—to accompany a cash prize was offered, which brought four competitors. Mr. McIntosh, gardener to J. T. Hingston, Esq., Clifton, York, easily secured first honours with a free arrangement of well-grown plants carrying blooms, the whole neatly margined with foliage plants. Mr. Kendall, gardener to J. M. Waddell, Esq., Selby, was second, the flowers in this group not being nearly so good as in the first prize lot. For a group of Chrysanthemums in a space of 80 square feet four competed, making in all a good display. Mr. Everard, gardener to Mrs. Gutch, York, won by the freshness of his blooms and the better arrangement. There was brisk competition in the class for four incurved distinct varieties. Mr. Everard won easily with rather tall but capitally flowered and neatly trained specimens of Prince Alfred, John Salter, and Jardin des Plantes. Mr. J. Smith, Beverley, was second with smaller yet capital plants. Mr. Everard secured the award for a specimen incurved, with Mrs. Dixon in good condition, carrying upwards of one hundred blooms.

The principal cut bloom class was that for twenty-four incurved, not less than eighteen varieties, and twenty-four Japanese, also in eighteen varieties. The handsome sum of £15 was given for the first prize, which brought five competitors, making in all a good display. Mr. Anderson, gardener to A. Milnthorpe, Esq., Cattal, York, was awarded first honours for a capital stand of Japanese blooms and large incurved, but the latter were getting old. The varieties were—Incurved—Back row: Queen of England (2), Lord Wolseley (2), Alfred Salter (2), Lord Alcester and Empress of India. Middle row: Lord Alcester, Pink Venus, White Venus, Nil Desperandum (2), John Salter, Mrs. Heale and Golden Empress. Front row: John Salter, Barbara, Cherub, Mr. Brunlees, Beauty, Sir S. Carey, Miss M. A. Haggas and Violet Tomlin. Japanese—Back row: Source d'Or (2), Meg Merrilies (2), Le Spectre Toulousain (2), Ralph Brocklebank (2), Mdme. C. Audiguier. Middle row: Fernand Feral, Comte de Germiny, Mrs. J. Wright, Edwin Molyneux, Avalanche (2), Comtesse de Beauregard Fair Maid of Guernsey, Val d'Andorre (2). Front row: Duchess of Albany, Mdle. Lacroix, Madame J. Laing, Martha Harding, Belle Paule. Mr. T. Caring, gardener to Mrs. Cope, Dove Park, Woolton, Liverpool, was a close second, losing by only two points, his incurved blooms, though smaller, possessing more finish, but the Japanese were not so large as those in the first prize stand. Mr. Coultas, gardener to W. Hardinge, Esq., Holly Hurst, Darlington, was third. Four competed in the class for twenty-four varieties, half to be incurved and the remainder Japanese. Mr. J. Smith, Norwood, took leading honours with even good stands of both kinds. Mr. Dickinson, gardener to W. B. Richardson, Esq., Elm Bunk, York, following with neat blooms. Mr. T. Smith, Norwood, Beverley, took leading honours for twelve incurved varieties, as he also did for six reflexed with medium size fresh examples.

Mr. W. Boston, Carthorpe, Bedale, with twelve Japanese, led the way with fresh medium-sized examples of leading varieties. For six Japanese, one variety, there was a brisk contest, and with well grown examples of Boule d'Or Mr. Anderson led the way amongst seven competitors; Mr. Dickinson was second with Ralph Brocklebank. Baskets of Chrysanthemums were numerous, as also were bouquets both of Chrysanthemums and miscellaneous flowers.

Fruit was not so abundant as on some previous occasions, but of capital quality. For six bunches of Grapes in three varieties there were five competitors. Mr. McIntosh, gardener to J. T. Hingston, Esq., York, took leading position with Gros Colman, capital in every respect, large in berry and of excellent colour; Alicante in a similar condition. Two splendid bunches of Trebbiano completed this collection. Mr. Dickinson took second honours, also staging well. For two bunches of white Grapes Mr. Hare, gardener to R. H. C. Neville, Esq., York, was well ahead with Muscat of Alexandria. For the same number of any black variety Mr. W. Jenkins, Aldin Grange Gardens, was an easy first among five others with magnificent examples of Gros Colman, having enormously large berries, well finished.

Vegetables were extremely abundant, and of good quality. Messrs. Backhouse & Son staged eighty dishes of Apples of the leading varieties in good condition, these being entered not for competition. The Exhibition reflected the utmost credit upon the energetic and courteous Secretary, Mr. J. Lazenby.

RUGBY.—NOV. 20TH AND 21ST.

THOUGH a comparatively young Society, that established in Rugby is giving substantial proof of its usefulness in improving the culture of Chrysanthemums in the district, and in developing a love of horticulture amongst amateurs. It fully deserves the strongest local support, as the funds are most judiciously expended, a comprehensive schedule is prepared, and the affairs of the Society are conducted by a practical Committee. The Chairman, Mr. L. Cumming, the Treasurer, the Rev. W. O. Wait, and the Secretary, Mr. W. Bryant, all work assiduously in advancing the Society's interests, Mr. Bryant, with some energetic members of the Committee, performing most useful service. The dates of this year's Show were unfortunately the same as those chosen for the Birmingham Exhibition, and this, in connection with the bad season, might have been expected to seriously affect it in the number of exhibits. With the exception, however, of one or two cut bloom classes there was no reduction of entries, and in some cases a very satisfactory increase was noticeable. Groups and plants were unusually numerous and good, the lower portion of the Town Hall being filled with exhibits. Miscellaneous plants, particularly Primulas and Cyclamens, were also well represented. The cut blooms, too, though not quite so abundant as at some previous shows, were fairly fresh and even throughout.

The principal class for cut blooms was for thirty-six (eighteen incurved and eighteen Japanese, distinct), a silver cup and £2 constituting the first prize, which was secured by Mr. W. Comfort, gardener to G. A. Everitt, Esq., Knowle Hall, Birmingham. The incurved were of medium size, but solid and neat, the varieties being in the back row: Golden Empress of India, Queen of England, Lord Alcester, Hero of Stoke Newington, Golden Queen of England, and Alfred Salter. Middle row: Jeanne d'Arc, Prince Alfred, Mrs. N. Davis, Miss M. A. Haggas, Princess of Teck, and Barbara. Front row: Violet Tomlin, Lord Eversley, Nil Desperandum, Cherub, Princess Beatrice, and Eve. The Japanese were fresh and bright, comprising in the back row: Boule d'Or, Comtesse de Beauregard, Gloriosum, Baronne de Prailly, Carew Underwood, and Meg Merrilies. Middle row: Madame C. Audiguier, Mdle. Lacroix, Madame J. Laing, Fair Maid of Guernsey, Sunflower, and La Triomphante. Front row: Mdle. Pigny, J. Délaux, Sarah Owen, Madame Baco, Mrs. J. Wright, and Thunberg. The second place was taken by Mr. W. Dillby, gardener to W. H. May, Esq., Bowden House, Market Harborough, who had small incurved, but good Japanese. The two competitors above named were placed in the same positions for twelve incurved, followed closely by Mr. J. Parker, Rugby. Mr. Comfort was in fact the most successful in the open classes, for he was first with twelve blooms (six reflexed and six Anemones); also with twelve Japanese and single blooms of incurved and Japanese, Empress of India and Meg Merrilies securing the last named honours, Mr. Parker following in some of the classes. A special prize was offered in a Rugby district class for twelve blooms, six incurved and six Japanese, distinct, which was adjudged to Mr. A. J. Kilbourn, Bilton Hall Gardens, who staged excellent specimens in both sections. The Rev. F. D. Morrice, Hillmorton Road, took the second place; Mr. Batchelor being third. Messrs. Kilbourn and Batchelor were also the prizetakers with twelve incurved in the order named. Classes were also provided for cottagers and amateurs, in which the competition was very good, and the exhibits in several cases of good quality. Bouquets were admirably shown by Messrs. Perkins & Son of Coventry, Mr. Parker also exhibiting well in the same class; while in another Mr. Arnsby and Mr. Batchelor secured the chief awards. Messrs. Perkins & Son also had a very tasteful basket of Chrysanthemums, being again followed by Mr. J. Parker.

Groups of Chrysanthemums occupied considerable space on the ground floor of the Town Hall, the chief class being that for a group arranged in a space of 60 square feet, and open to all exhibitors. Mr. J. Parker won the first place easily with a very tasteful arrangement, the plants dwarf in front, the blooms good and varied, and the whole most satisfactory. Mr. Kilbourn was second, his plants having fine blooms, and brightly coloured varieties being freely employed it was

very effective. Mr. Andrews had the third place, his blooms being somewhat small, but general style was good. In the district class for a group in a similar space the Rev. E. P. Morrice led with a most effective, bright, and handsome group, the plants dwarf. The Rev. D. Percival also exhibited well in this class. The Chrysanthemum plant classes brought numerous exhibits from Messrs. Newman, Tunnard, Killbourn, Parker, Batchelor, Oldham, and Daniels. In the single trained specimen class Mr. J. Newman, gardener to Mrs. Morgan Molesworthy, The Hollies, Bilton Road, showing Guernsey Nugget, a fresh, evenly trained, healthy, and well flowered plant. Mr. Andrews was second, also with a good specimen.

Primulas from Messrs. Batchelor, Parker, Daniels, Barber, Arnsby, and the Rev. Payne Smith were good. Apples and Pears and Grapes were shown in small numbers but of fairly good quality, Messrs. Comfort, Hancox, Parker, and Bottrill taking the chief prizes. Vegetables were excellent, and in close competition Messrs. Hancox, Batchelor, Howes, Hall, Arnsby, and Morris and Daniels won the leading prizes.

Noticeable amongst the non-competing exhibits was an extensive group of Chrysanthemums and foliage plants arranged at one end of the upper hall by Mr. J. Parker, which was very highly commended.

BRISTOL.—NOVEMBER 20TH AND 21ST.

THIS, for a southern Show, was a decided late fixture, but the entries were nearly as numerous as usual, while the quality of the exhibits, with one or two exceptions, was fully up to the average. The Show was well arranged by Mr. Wilfrid Jones, the Secretary, and his practical assistants.

Trained Chrysanthemums were scarcely so good as they have been seen at former shows, but were highly creditable. The best six specimens of large flowering varieties were staged by Mr. J. Lee, gardener to T. M. Miller, Esq., who had Mrs. Forsyth, Mrs. Dixon, Barbara, Mrs. G. Rundle, Christine, and Guernsey Nugget in excellent condition. Mr. H. Hanking, gardener to J. Leech, Esq., was a good second, and Mr. G. Silcock, gardener to W. Vowles, Esq., third. Mr. Lee was also well first for six Japanese varieties, these consisting of Souvenir de Haarlem, Irene, Fair Maid of Guernsey, Bertier Rendatler, Janira, and Source d'Or. Messrs. Hanking and Silcock were respectively second and third, both having several fresh creditable specimens of popular varieties. The three best standard trained plants were shown by Mr. Hanking; Mr. W. H. Bannister, gardener to H. St. V. Ames, Esq., being a fairly good second. Plants in 8-inch pots were well shown, the majority of them having good foliage and perfect flowers. Mr. Hanking was first, Dr. R. A. Ross second, and Mr. G. Silcock third. There were two classes provided for groups of Chrysanthemums, and the competition was keen. With the largest, or those to occupy a space 12 feet by 7 feet, Mr. A. Parkes, gardener to Thomas Owen, Esq., was well first, many fine blooms being shown in his group. Mr. W. Marshall, gardener to James Dole, Esq., was a good second; and Mr. T. Arwell, gardener to T. B. Bran, Esq., third. Mr. E. T. Hill was rightly awarded a first prize for a smaller group. Numerous classes were provided for miscellaneous plants, in most of which the competition was close and good. The first prize for a group to occupy a space 10 feet by 5 feet was well won by Mr. J. Ayres, gardener to T. W. Gibson, Esq., who had a bright pleasing arrangement. Mr. J. Aswell was second, and Mr. Hancock, gardener to A. W. Summers, Esq., third. The principal prizewinners in the other plant classes were Messrs. Lee, Hancox, Shelton, gardener to W. R. Wait, Esq.; Bannister, Aswell, R. Cripps, G. White, G. Harris, and A. Parkes.

Ten classes were provided for cut blooms, in each of which, in spite of the comparative lowness of the prizes offered, the competition was very keen, several quite new exhibitors coming to the front with exhibits that would have gained prizes at earlier shows. The first prize, a silver cup, value three guineas, offered for twenty-four large-flowered Chrysanthemums in not less than eighteen distinct varieties, was awarded to Mr. C. Cooper, gardener to C. L. Collard, Esq., Taunton, his stands containing excellent blooms of the leading varieties. Mr. A. Parkes was second, and Mr. J. Applin, gardener to W. M. Baker, Esq., third, both having many perfect blooms. Mr. Cooper was also first for twelve incurved varieties, these consisting of Mrs. Norman Davis, Empress of India, A. Salter, Empress Eugénie, Golden Empress, Princess of Teck, Mr. Howe, Barbara, Jeanne d'Arc, Princess of Wales, and Jardin des Plantes, all fresh and good. Mr. A. Parkes was again a close second, and Mr. J. Applin third. Japanese varieties were most extensively shown, several excellent stands not gaining a prize. With twenty-four blooms in not less than eighteen varieties, Mr. Cooper again came in first with blooms in fine condition. Mr. J. Applin was a close second, and Mr. John Austin third. With twelve varieties Mr. Applin was first, his generally excellent exhibit including good blooms of Gladiator, Mrs. A. Harris, Mr. Thomson, Mr. H. Cannell, and Mad. Baco. Mr. Cooper was second, and Mr. Runnales, gardener to C. Thurburn Esq., third. Mr. Parkes staged remarkably good blooms of Empress of India, Lord Alcester, and Lord Wolseley in the class provided for these varieties, and was first, Mr. W. Carpenter, gardener to A. Cole, Esq., being second. Several exhibitors misread the schedule, staging one only of the three varieties named, the same thing occurring in the class provided for two blooms each of E. Molyneux, Carew Underwood, and R. Brocklebank, the consequence being that some of the finest blooms seen in the Show gained no awards.

Bouquets, wreaths, and vases of choice flowers and baskets of autumn foliage and fruit are always well shown at the Bristol Chrysanthemum Shows. Mr. C. Winstone, Clifton, was the most successful competitor, but Messrs. Garaway & Co. also had a very beautiful wreath, and abund-

ance of very choice flowers in their second prize bouquet. Other successful exhibitors in these classes were Messrs. M. Hoskings, E. T. Hill, T. Meakins, and J. C. Aiken.

The first prize for a collection of six varieties of fruit was well won by Mr. W. Nash, gardener to the Duke of Beaufort, who had good Alicante and Muscat of Alexandria Grapes, a Melon, Pears, Apples, and Medlars, all in excellent condition. Mr. Bannister was second. The first prize Muscat of Alexandria and Lady Downe's Grapes shown by Mr. J. Gibson, gardener to Lord Cowley, and Mr. Nash's Gros Colman Grapes were decidedly superior. Other successful exhibitors of Grapes and also Apples and Pears, were Messrs. Bannister, J. F. Wilkinson, G. Pym, W. Iggluden, E. Hall, E. T. Hill, C. Cooper, J. Rogers, and A. Miller, gardener to W. H. Long, Esq. Mr. J. Austin had a first prize for a very fine Smooth Cayenne Pine Apple. The best collection of ten varieties of vegetables, and for which the prizes were provided by Messrs. Sutton and Sons, was shown by Mr. J. H. Virgo, Mr. Bannister being a good second. Mr. R. Cripps was first, and Mr. J. W. Virgo second, for six varieties of vegetables.

The most noteworthy among non-competitive exhibits was a large group of healthy, fine-foliaged, and flowering plants, contributed by Messrs. G. Garaway & Co., Durdham Down Nurseries, Clifton, this firm also having an attractive exhibit of cut blooms of Chrysanthemums, which comprised many valuable new and the best of the old varieties found in each section.

THE NATIONAL CHRYSANTHEMUM SOCIETY'S PROVINCIAL SHOW AT HULL.—NOVEMBER 21ST AND 22ND.

CONSIDERING the earliness of the season and the somewhat late date of the Show, also the overlapping of the Birmingham Exhibition, there was a little fear lest the Hull gathering would not be equal to those of former years. It was a distinct advance on last season's display, while the shows of some previous years were weak in comparison. Mr. Holmes pronounced this, the second provincial Show of the N.C.S., a great and gratifying success, quite exceeding his expectations. No Exhibition could be better managed, the President, Secretaries, Treasurer, and members of the Committee all working zealously on well organised lines, and the Judges were at work at 10.30. The Exhibition was opened by the Mayor in a singularly able and interesting speech, and the several cups were presented by the Mayoress to the respective winners of them, on the orchestra, in the presence of a crowd of visitors. The attendance was large throughout, and on the second day children from the orphanage, deaf and dumb schools, workhouse, &c., were made happy by a march through the great Exhibition. The groups were numerous and fine, some of the specimen plants excellent, and 2304 cut blooms were staged, an increase of 569 on the number last year. We are glad to hear that the Show was a financial success. The total number of visitors to the Show during the two days was over 10,000, including 600 charity children and their teachers, admitted free on the morning of the second day. Only a condensed report can be given of so large an exhibition.

The Judges were Mr. John Wright, Mr. George Gordon, Mr. R. Dean, and Mr. Lewis Castle.

PLANTS.

The large entrance hall was extremely gay with three central miscellaneous groups, raised 18 inches from the floor, and effective, six imposing collections of Chrysanthemums, Palms, Ferns, and foliage plants, being arranged along the sides of the building. In the Chrysanthemum group class first honours fell to Mr. J. P. Leadbetter, gardener to Anthur Wilson, Esq., Tranby Croft, with a splendid assortment remarkable for the excellence of the blooms and neat margin. The only fault was a suspicion of stiffness through somewhat too upright staking of a few of the plants, still it was well worthy of the cup it won. Mr. Cottam's second prize group was quite as well arranged, sloping from a height of 9 feet at the apex to the ground, flowers and foliage being tastefully associated, but as evidently most of the Chrysanthemum blooms were from late, or terminal buds, the flowers were necessarily somewhat small. The third prize fell to Mr. R. Willey, gardener to W. Wheatley, Esq., Anlaby Road, Hull, and fourth to Mr. G. Jarvis, gardener to B. Whitaker, Esq., Hessle, with heavy blooms, but too early for the date of the Show.

In the miscellaneous group class the first prize was well won by Mr. E. Wright, gardener to David Wilson, Esq., Park House, Cottingham, with a charming association of Palms, Ferns, Poinsettias, Calanthes, and Callas; and a pleasing margin of Isoplepis, Panicum, and other dwarf plants. Mr. G. Cottam, jun., Cottingham, was an excellent second, and Mr. H. H. Taylor third. Messrs. E. P. Dixon & Sons exhibited a handsome group of plants not for competition, and an excellent assortment of Apples and Pears.

For three trained specimen Chrysanthemums Mr. J. S. Graham, gardener to G. Lawson, Esq., Newland Grove, Hull, secured the chief position with Mr. G. Glenny, Mrs. G. Rundle, and Mrs. Dixon, bearing from sixty to a hundred blooms each, fresh and fine, the plants being also excellent in foliage and training, the trio being quite worthy of a place at any exhibition in the kingdom. His three standards, which also well won the chief prize in the class, were not less remarkable for the superiority of the blooms and general good quality. Mr. Graham was first in the specimen plant class with a beautiful example of Mrs. G. Rundle. Other successful prizetakers in those classes were Mr. H. H. Taylor, Newland; Mr. W. Mason, gardener to A. K. Dibb, Esq., Kirk Ella; Mr. G. Jarvis; and Mr. J. A. Thompson, Hessle. In the class for six bush-grown but not formally trained plants there was excellent

competition, the first prize being admirably won by Mr. G. Hemming, gardener to E. Leetham, Esq., Beechholme, Newland; his Chevalier Domage, with rich foliage and twenty to thirty bright blooms, was a model conservatory plant, and the others were good. Mr. H. H. Taylor was a close and excellent second, and Mr. G. Hancock, Beverley, a creditable third. The worst plants in this class were far better than the best were a few years ago. There were many other creditable exhibits, but we must pass to another section.

CUT BLOOMS.

Liberal provision was made in the schedule for cut blooms, thirty-six classes being devoted to them, with many prizes ranging from £15 to 1s., besides five silver cups, value from fifteen to five guineas. Every inducement was, in fact, offered to exhibitors, and taking the disadvantageous season into consideration the results in numbers and quality were very satisfactory. When it was found that some of the best collections in the kingdom were becoming decimated by the evil effects of "damp" the prospects of the later shows were far from encouraging, and it was thought at one time that the majority would prove positive failures. Happily these forebodings were not realised, and though the competition has necessarily been more restricted, still there has been sufficient in the best classes to awaken considerable interest.

At Hull a good show of cut blooms has been annually produced for some years past, and those who looked for a repetition of previous successes were not disappointed. The leading class was that for forty-eight blooms, twenty-four incurved and the same number of Japanese in not less than eighteen varieties each, the fifteen-guinea silver challenge cup, offered by Lieut.-Col. Gleadow, and £15 constituting the premier, with £10, £5, and £2 as second, third, and fourth prizes. There were only four competitors, the premier position being accorded to Mr. Peter Blair, gardener to the Duke of Sutherland, Trentham, for substantial well-finished blooms of the following. Incurved:—Back row: Lord Alcester, Golden Empress of India, Alfred Salter, Empress of India, and Golden Empress of India, Queen of England, Bronze Queen, and Lord Alcester. Middle row: Bronze Queen, Lord Wolseley, Miss M. A. Haggas, Queen of England, John Salter, Mrs. Heale, Emily Dale, and Empress of India. Front row: Mabel Ward, Emily Dale, Princess Teck, Hero of Stoke Newington, Mr. Bunn, Lady Dorothy, Princess of Wales, and Cherub. The Japanese were of excellent size and colour, and even throughout the stand. The varieties were—Back row: Etoile de Lyon, E. Molyneux, Stanstead White, Boule d'Or, G. Daniels, Val d'Andorre, Ralph Brocklebank, and Etoile de Lyon. Middle row: Boule d'Or, Meg Merrilies, Belle Paulc, Meg Merrilies, Triomphe de la rue des Châlets, Avalanche, Belle Paule, and Fair Maid of Guernsey. Front row: Moonlight, Madame C. Audiguier, Sarah Owen, Stanstead Surprise, Gloriosum, Madame J. Laing, Sunflower, and J. Délaux. The second prize was secured by Mr. D. Heany, gardener to H. G. Schintz, Esq., Mossley House, Park Avenue, Mossley Hill, in a close competition, necessitating careful pointing to determine the relative positions of the second and third prize stands. Mr. Heany's Japanese were very strong, the blooms large and of capital colour; Etoile de Lyon, Sunflower, and Stanstead White were very notable. Mr. Leadbetter, gardener to Arthur Wilson, Esq., Tranby Croft, Hull, was third; and Mr. Goodacre, gardener to the Earl of Harrington, Elvaston Castle, was fourth, with rather small incurved but fresh and good Japanese.

In the next class, that for twenty-four blooms—twelve incurved in not less than nine varieties and the same number of Japanese—there were six competitors. Mr. P. Blair was again adjudged the first prize and a silver cup offered by the Mayor of Hull, J. Sherburn, Esq., for creditable blooms of incurved—Back row: Lord Alcester, Golden Empress, Queen of England, and Empress of India. Middle row: Bronze Queen, Empress of India, Lord Alcester, and Golden Empress of India. Front row: Mrs. Heale, Barbara, Hero of Stoke Newington, and Emily Dale. Japanese.—Back row: G. Daniels, Ralph Brocklebank, W. G. Drover, and Stanstead White. Middle row: Avalanche, Belle Paule, Fair Maid of Guernsey, and Madame J. Laing. Front row: Gloriosum, Val d'Andorre, Madame J. Laing, and Boule d'Or. The second prize was secured by Mr. Leadbetter, who had excellent Japanese and small but even incurved. The third place was taken by F. H. Anthony, Esq., Knighton Church Road, Leicester, with fresh and even blooms of moderate size; and Mr. G. Appleton, gardener to C. H. Johnson, Esq., Thorngumhold Hall, Hull, was fourth.

A silver cup value 5 guineas, offered by the Sheriff of Hull, Arthur Wilson, Esq., contributed the first prize (with £5 in cash) in class 3 for twenty-four Japanese in not less than eighteen varieties. This was awarded to Mr. Heany with bright fresh well developed blooms representing most of the best varieties. Mr. Anthony was second, and Mr. Goodacre third. Six competitors staged in the class for twelve Japanese, distinct, Mr. J. Hare, gardener to J. H. Hudson, Esq., Longcroft, Beverley, winning the first prize with an admirable collection. Mr. Wilton, gardener to G. A. Carr, Esq., Waltham Grove, Grimsby, was a close second; and Mr. Heany third.

Several classes were devoted to incurved blooms, Mr. Heany gaining first honours for twenty-four blooms in not less than eighteen varieties, thereby securing £5 and the National Chrysanthemum Society's silver-gilt medal. He exhibited fairly good blooms well finished and effectively staged. Only one other collection was shown, and that was considered unworthy of a prize. Five exhibitors of twelve incurved in nine varieties staged fairly good blooms. Mr. G. Blatherwick, gardener to H. Wilson, Esq., Cottingham House, Cottingham, won easily with fine examples of Alfred Salter, Golden Empress (3), Lord Alcester (2),

Empress of India, Jeanne d'Arc, Princess of Wales, Lord Wolseley, Queen of England, and Barbara. Mr. Heany, and Mr. E. Wright, gardener to D. Wilson, Esq., Park House, Cottingham.

A class was provided for twelve reflexed blooms, not less than nine varieties, and of the five stands exhibited the blooms from Mr. R. Walker, gardener to Col. Stracey Clithcrow, Hotham Hall, Brough, were found to be the best, capital examples of Cullingfordi, Golden White, Blush Christine, Cloth of Gold, Annie Salter, and Chevalier Domage. Mr. J. Hare and Mr. Davidson, gardener to F. W. Jameson, Esq., Eastella, near Hull. For twelve Japanese, reflexed, in six varieties, Mr. Appleton took the premier place, showing good blooms of J. Délaux, Blaine, Criterion, La Triomphante, Maiden's Blush, M. Astorg and M. Jacotot.

Large Anemones had a class devoted to them, twelve blooms being required in not less than nine varieties, and the great attraction was a five-guinea silver cup offered by Mr. E. C. Jukes, Vice-Chairman of the National Society, and formerly a resident in Hull. The stipulation was attached, however, there must not be less than six competitors, and it at one time became a little doubtful if that condition would be complied with. However, the necessary entries were eventually obtained, and Mr. F. W. Jameson was successful in winning the cup and first prize with excellent blooms, high in the centre, clear distinct colours, and fresh. The chief varieties were Miss Annie Lowe, La Marguerite, Sabine, Lady Margaret, Gluck, Emperor, Acquisition, and M. Pankouke. Mr. F. Mason, gardener to G. Bohn, Esq., Tranby Park, Hessle, and Mr. G. Herdsman, gardener to J. H. Fisher, Esq., Willerhy Hall, were second and third. For twelve Japanese Anemones, in eight varieties, Mr. Mason led with well developed flowers of Jeanne Marty, Sœur Dorothee de Souille, Ratapail, Madame Clos, Minnie Chate, Marguerite Villageoise, and Madame B. Pigny. Mr. F. W. Jameson was a close second, and Mr. Herdsman third. Of four stands of Pompons the best was that shown by Mr. Wilkinson, gardener to Mrs. Ross, Elloughton Lodge, Brough, who had two capital back rows, comprising Golden and White Madame Marthe, Cressus, Black Douglas, Rosinante, Elise Layeillon, Adèle Prissette, and small example of Snowdrop, Trophée, Pink Trevenna, and La Vogue. Mr. G. E. Smith was second also with two good back rows. Mr. J. Hemming, gardener to E. Leetham, Esq., Beechholme, Newland, was third with large but rather coarse blooms.

Pompon Anemones were admirably represented in a premier stand from Mr. Harry Harland, The Sycamores, Cottingham. The varieties Antonius, Mrs. Wyness, Madame Montels, Regulus, Calliope, Madame Chalonge, and Marguerite de Coi were especially good. A class was provided for sweet-scented Chrysanthemums, but few of the seven entries were satisfactory, and several examples of Progne were quite devoid of fragrance. A bunch of single varieties from Mr. H. W. Stanley De-la-Pole, Avenue Hall, was selected as possessing the most pleasant odour. Mr. G. E. Smith was second with a blush reflexed variety, and Mr. Walker third with good blooms of Progne. Single varieties formed an attractive class. Mr. G. E. Smith won the first place amongst four competitors, and had an excellent collection, including several promising seedlings, one of which, Ethel Smith, with soft pink florets, white at the base, received a first class certificate from the Floral Committee. The other varieties were Patience, Master Frank, Arthur, Lady Brassey, Magenta King, King of the Yellows, and Mary Anderson. Messrs. E. Goddard and Harry Harland were second and third. The finest six incurved blooms of one variety were shown by Mr. Blair, the variety being Golden Empress, and Mr. Graham followed with Lord Alcester. In a corresponding class for six Japanese Mr. Coates was first for deep substantial blooms of Avalanche. Mr. Burrows followed with Boule d'Or, and Mr. Walker third for Madame C. Audiguier. The class for six bunches of Mrs. G. Rundle, Mrs. Dixon, and G. Glenny was a good one, the eight competitors all showing good blooms of the useful varieties named. Messrs. Graham, Smith, and Taylor were the prize-takers in the order mentioned. A silver cup, offered by Messrs. E. P. Dixon & Sons, for twenty-four blooms (twelve incurved and twelve Japanese, six varieties each) was adjudged to Mr. Blatherwick, who had the best blooms amongst seven competitors, fresh well-developed blooms in both cases, Messrs. Hotham and Walker following.

The amateurs' classes for cut blooms were well filled, and the exhibits were of good quality in the majority of cases. The following competitors secured the chief prizes:—Messrs. A. W. Stanley, S. Higham, J. Melbourne, G. F. Grant, J. W. Briggs, R. R. Risdale, H. Willford, T. Maplebeck, G. Hancock, R. B. Chapman, W. Howell, E. Goddard, and J. W. Robinson.

Premier Blooms.—In the open classes the prizes for the best incurved were granted to Mr. Blair for Golden Empress, for Japanese to Mr. Heany for Etoile de Lyon. In the amateurs' classes to Mr. Stanley for Barbara, and to Mr. Howell for Boule d'Or.

Mr. Morton, Darlington, exhibited a good and varied collection of blooms not for competition.

A large annexe was devoted to floral decorations, in which Chrysanthemums were chiefly employed, and these constituted together a very pleasing portion of the Exhibition. The tables were the least satisfactory, however, as all, including the prizewinners, were defective in some particulars.

In the evening of the opening day a Conference was held in the Hull and East Riding College, Mr. R. F. Jameson presiding, when excellent papers were read by Mr. George Gordon and Mr. John Wright that were followed by a prolonged and important discussion. There was a large attendance of amateurs and gardeners, and the meeting was one of the most satisfactory yet held.

SHEFFIELD AND WEST RIDING.—NOVEMBER 22ND AND 23RD.

THE fifth annual Show of this Society was held on the above dates in the spacious Corn Exchange, than which a more suitable building for the purpose of such a display could scarcely be found. The Show was in all respects superior in general effect, as well as in both quantity and quality of the plants and cut flowers exhibited, to any of those previously held by the Society, and reflected most creditably upon the energy and tact which has been displayed in carrying it to so successful an issue by the officials and Committee, and especially the indefatigable and courteous Secretary, Mr. W. Housley, and the Hon. Treasurer, Mr. H. Broomhead. A most comprehensive and liberal schedule had been provided, an aggregate sum of close upon £200 being offered in prizes.

In the open classes for cut flowers exceptionally liberal prizes were offered—viz., a silver cup value £10 10s. and £5 in cash for twenty-four incurved flowers, and a like silver cup and cash prize for twenty-four Japanese cut flowers. These prizes brought together five competitors in each class, most of them well known men in the Chrysanthemum world, as Mr. Parker, Impney; Mr. Lambert, Onslow Hall, Shrewsbury; Mr. Cox, Wavertree, Liverpool; Mr. Goodacre, Elvaston Castle, Derby; and Mr. Green, Shirecliffe Hall Gardens, Sheffield. In the class for twenty-four incurved, not less than eighteen varieties, Mr. John Lambert, gardener to Col. Wingfield, was placed first with smooth, solid, fresh blooms, the varieties being similar to those in his Leicester stand. The second prize in this class was obtained by Mr. R. Parker, and the third by Mr. R. Cox. Very little disparity in merit existed between these stands or between the corresponding stands in the Japanese class, and the Judges found considerable work in justly apportioning the prizes. In the class for twenty-four Japanese blooms, not less than eighteen varieties, Mr. Parker was placed first, his blooms having a little the advantage in size and weight over those of his opponent's. His varieties were much the same as he staged at Birmingham. In the open class for twelve incurved blooms Mr. Lambert was again first, his blooms being excellent. Twelve Japanese, distinct.—First, Mr. A. R. Cox, with Sunflower, Meg Merrilies, Japonais, Comte de Germiny, Madame J. Laing, Charlie Sharman, Mdle. Lacroix, Madame C. Audiguier, Val d'Andorre, Boule d'Or, Jeanne Délaux, and Ralph Brocklebank. In this, as in his stand of twenty-four, Mr. Cox's Japanese flowers were exceedingly young, fresh, and brightly coloured, but not quite of the largest size.

In the district classes, open to growers residing within a radius of twenty miles from Sheffield, there was good competition, and the flowers shown by several exhibitors were but little inferior to those shown in the open classes. Mr. Green, Shirecliffe Hall Gardens, and Mr. James Harrison, Walkley, were the most successful exhibitors with very large and good blooms. In the amateur and cottager classes, "open only to those who do not employ a gardener," there was an immensely keen competition, and numbers of very good flowers staged. In the smaller classes, for six and three flowers in each, there were upwards of twenty competitors, as many as eight prizes being awarded in each class. Striking improvement was manifest in the general quality of the flowers shown in these classes over the exhibits by the same growers in previous years.

In the classes for plants and groups again a decided improvement was noticeable over previous years' exhibits. Groups were especially well shown, both those for Chrysanthemums and those for miscellaneous plants. In the class for a group of Chrysanthemums, occupying space of 64 square feet, Mr. Pidsley, gardener to Mrs. H. Wilson, Westbrook, was placed first, Mr. Green second, and Mr. J. Harrison third. In the class for miscellaneous groups Mr. Pidsley was again first with a beautiful arrangement, which elicited much admiration. Mr. W. Collier, gardener to Mr. J. Eaton, Sharrow Bank, was placed second with an excellent group, but rather too closely packed. Amateurs' groups (miscellaneous plants) were numerous and good. In these Mr. M. Taylor was first, Mr. G. S. Stocks second, Mr. R. Gascoyne third, and Mr. J. Swinden fourth.

The specimen plants shown were throughout better than last and preceding years, Messrs. C. Green and E. Pidsley being the principal prizewinners. Excellent groups, not for competition, were staged by Messrs. Fisher, Son, & Sibray, Handsworth Nurseries; Messrs. H. Shaw and Son, Richmond; Mr. B. Crossland, Richmond; Mr. D. B. Fellowes, Pitsmoor; and Mr. S. Seagrave, nurseryman, Gleadless. Primulas were numerous and of high quality. The same may also be said of Ferns, British and exotic, Mr. John Eadon—a name well known to growers of British Ferns, being the most prominent prizewinner, with large plants of choice and rare varieties, all in the most vigorous health.

Certificates were awarded to Mr. S. Coleman, a pleasing bronze sport from Princess of Wales (incurved), exhibited by Mr. R. Owen; and to Mr. R. Hartland for a patent method of holding tubes in flower boards immovable.

The Show was opened to the public at 1 P.M. on the 22nd, by the President of the Society, Mark Firth, Esq., assisted by Sir H. E. Watson, Sir H. Stephenson, and other gentlemen. There was a crowded attendance on the evening of the second day, but only a moderate one during the first day.

LOUGHBOROUGH.—NOVEMBER 23RD.

THE fifteenth Show was held in the Town Hall, when, considering the lateness of the date, the blooms were in good condition. The groups of Messrs. J. Smith and J. & H. Hickling were especially good, and worthy of a higher prize. Messrs. F. J. Rowbotham and E. Whelland were the most successful exhibitors of specimen plants. In the class for eighteen blooms, incurved, distinct, Mr. J. Beeby, gardener to the Rev.

J. Bird, was first with Lord Alcester, Alfred Salter, Emily Dale, Lord Wolsely, Empress of India, Queen of England, Brouze Jardin des Plantes, Jeanne d'Arc, Princess of Wales, John Salter (good), Empress Eugénie, Mr. W. Shipman, Lady Slade, Barbara, Princess of Teck, Lady Hardinge, Eve, and Prince of Wales. Second, Mr. J. Smith, who had a very good Hero of Stoke Newington. Third, Messrs. J. & H. Hickling. Twelve blooms, incurved.—Rev. J. Bird was first with Empress of India, Alfred Salter, Lord Alcester, Queen of England, J. Salter, Emily Dale, Lord Wolsely, Princess of Wales, Lady Hardinge, Mr. Shipman, Jeanne d'Arc, and Barbara. Second, Mr. J. Smith. Third, J. & H. Hickling. Six blooms, incurved.—Rev. J. Bird was again first with a good stand, Messrs. J. Smith and A. Squires following. Twelve blooms, Japanese.—First, Mr. W. S. Botton, gardener to Major O'Neal, Ratcliffe Hall, who had Boule d'Or, Avalanche, Ralph Brocklebank, Meg Merrilies, Baronne de Prailly, Japonais, Val d'Andorre, Gloriosum, Golden Dragon, J. Délaux, Fair Maid of Guernsey, Criterion. Second, Mr. J. Smith. Third, Rev. J. Bird. Mr. Bolton was also first with six blooms, Rev. J. Bird second, Mr. J. Smith third.

Bouquets of Chrysanthemums, with Grapes, Apples, and Pears were well represented, but cannot be more particularly referred to.

BIRMINGHAM.—Nov. 20TH AND 21ST.

THE twenty-ninth annual Exhibition is now a thing of the past, and the Committee were fortunate in having two days of mild dry weather, and an enormous crowd of visitors on each day. Of the Exhibition we must speak in the highest terms of praise, and this opinion was universal amongst the visitors. The Society has a large body of subscribers, somewhere about 350, and a large number of tickets are sold beforehand, so that the actual income of the Society for 1889 cannot yet be told until the accounts are made up, but some idea may be formed of the great increase this year from the following statement. The money taken at the doors for admission amounted in 1887 and 1888 to just about £170 each year, whilst for the current year the takings at the doors at the recent show amounted to close upon £280; and at times during the evening, such was the great pressure in the crowd of the visitors, the doors had to be closed, and a great many either left the Hall very soon after going in, or could not go in at all.

The blue riband of the Exhibition was the £25 first prize for forty-eight blooms, twenty-four incurved and twenty-four Japanese, and it brought eight exhibitors, and, taking the blooms generally, we are bound to say that they were fine. The first and second prize lots were extremely close together in size and quality, the first to Mr. Parker, gardener to J. Corbett, Esq., M.P., Impney, Droitwich, with the following varieties:—Incurved—Back row: Queen of England, Emily Dale, Alfred Salter, Miss Haggas, Princess Teck, Empress of India, Golden Empress, Lord Alcester. Middle row: Charles Gibson, Lady Hardinge, Mrs. Heale, Lord Wolsely, Prince Alfred, Princess of Wales, Hero of Stoke Newington, Jeanne d'Arc. Front row: Refulgens, Mrs. Shipman, fine; Mr. Brunlees, Lord Eversley, Mrs. N. Davis, Violet Tomlin, Cherub, and one other whose name we could not get. Japanese:—Back row: Boule d'Or, E. Molyneux, Avalanche, Sunflower, Triomphe de la rue des Châlets, Gloriosum, Fair Maid of Guernsey, Madame C. Audiguier. Middle row: Mons. Bernard, Meg Merrilies, Carew Underwood, Mr. Henry Cannell, Madame Laing, Mdle. Lacroix, Criterion, Ralph Brocklebank. Front row: Thunberg, Ed. Audiguier, Mrs. Henry Cannell, Sarah Owen, Florence Percy, Duchess of Albany. Second prize, £15, Mr. W. Marshall, Uttoxeter, in whose stand were especially fine flowers of Etoile de Lyon, Triomphe de la rue des Châlets, Mrs. Norman Davis, Lady Carey, Cherub, and Princess of Teck. Third, Col. Wingfield, Shrewsbury (gardener, Mr. J. Lambert) a very fine lot. Fourth, Sir T. E. Moss, Bart. (gardener, Mr. Lindsay); fifth, Sir Richard Moore, Bart., Coventry; sixth, Lord Heytesbury (gardener, Mr. J. Horsefield). There were eight exhibits in this class, and these special Centenary prizes had been raised chiefly by private subscriptions obtained by Mr. J. Hughes, the energetic Secretary of the Society. The sum of £54 10s. was expended in these six prizes.

For twenty-four blooms, twelve incurved and twelve Japanese, there were several exhibitors. Here again Mr. Parker secured the first prize with a fine lot of blooms—viz., Japanese:—E. Molyneux, Gloriosum, Madame C. Audiguier, Meg Merrilies, Sunflower, Souvenir de la rue des Châlets, Boule d'Or, Jeanne Délaux, Mrs. H. Cannell, Thunberg, Duchess of Albany, and Avalanche. Incurved.—Princess Teck, Lord Alcester, Queen of England, Golden Empress, Miss Haggas, Violet Tomlin, Mrs. Heale, Princess of Wales, Hero of Stoke Newington, Charles Gibson, Mr. R. Davis, and Lord Eversley. Second, Mr. C. H. Wright, Oswestry. In this stand was a grand bloom of Etoile de Lyon, but almost white. In Mr. Wright's stand we noticed very fine blooms of Avalanche and Madame Louise Leroy. Third, Mr. Austin, gardener to the Earl of Dudley, Witely Court. In the class for eighteen incurved Chrysanthemums Mr. Parker was again first with a very fine stand. Second, Mr. W. Marshall. Third, the Earl of Dudley. For twelve blooms, Japanese, first the Earl of Dudley; second, Mr. Parker; third, Mr. Coombe, gardener to the Countess of Dudley, Himley. In the class for twelve Anemone flowered Mr. Coombe staged a beautiful stand of flowers, which were much admired—viz., Monsieur Cabrol (2), Fabian de Mediana (2), Miss Annie Lowe (2), the latter a lovely creamy-coloured flower; Souvenir de Madame Blandinières, Duchess of Edinburgh, Georges Sand, distinct and good; Fleur de Marie, Princess Louise, and Acquisition. In Class 14, for twelve Japanese and twelve incurved grown in Birmingham, Mr. O. Brasier, gardener to Sir Thomas Mar-

tineau, was first with a superb lot of flowers, and he also carried off the first prize for twenty-four blooms grown in Birmingham.

There were two classes for groups of Chrysanthemums, Mr. Cooper, gardener to the Right Hon. Joseph Chamberlain, M.P., being a good first with a very telling group; and Mr. Brasier, gardener to Sir Thomas Martineau, second; Mr. F. A. Walton third. There were seven exhibitors, Mr. W. H. Dyer, gardener to Mrs. Marigold, Edgbaston, taking the first prize.

Birmingham has always been noted for the excellence of Chrysanthemums in pots. Four nines were staged, and Mr. Cooper, gardener to the Right Hon. Joseph Chamberlain, M.P., was first for very fine specimens, as well as for six plants. Sir Thomas Martineau's second prize nine were admirable, and Mr. Denning a good third. Mr. Dyer, to whom an extra prize was awarded, was too early for the Show, his plants being at their best a fortnight since. Other classes for Chrysanthemums in pots were well filled. Three collections of six ornamental plants were staged, all first rate. Mr. Dyer scored first, and had two magnificent Crotons, Queen Victoria and C. Weismanni.

Two lots of six Orchids were staged. First prize Mr. Barnes, gardener to Charles Winn, Esq., Selly Oak, with a large lot of *Cypripedium Spicerianum*, *C. Sedeni*, *Oncidium tigrinum*, a fine example of *Calanthe Veitchi*, *Masdevallia Veitchi grandiflora*, and another Orchid. Second, G. H. Kenrick, Esq., Edgbaston (Mr. W. A. Powell, gardener). Messrs. Heath & Son, nurserymen, Cheltenham, sent a few Orchids, amongst them a plant of *Lælia Tresederiana*, so named by Professor Reichenbach, to which a certificate was awarded.

Primulas were to the front. They are always shown well at Birmingham: 330 plants were staged in competition for the various prizes, and they were a splendid lot. In the open classes Messrs. Thomson and Co., nursery and seedsmen, Birmingham, took the first prize for twelve and six plants of singles, Messrs. Pope & Sons second. For six doubles Messrs. Thomson first, as well as for six Fern-leaved varieties, and also taking the premier prize for the best single Primula in the Exhibition, a fine plant of *Empress* with exquisitely tinted flowers. In the gentlemen's gardeners' class for twelve single Primulas Sir Thomas Martineau's gardener was first, and for six single Primulas first Mr. Cooper. Then there are special prizes given by Messrs. Thomson & Co. and Messrs. Pope & Sons for Primulas, and plenty of exhibits resulted. For six dinner table plants several lots were staged, all so suitable, light and elegant. Bouquets were remarkable for their quality and beauty; there were two classes, one for nurserymen only. First, Messrs. Perkins & Sons, Coventry. Second, Messrs. Pope & Sons, Birmingham. Third, Messrs. Jones & Sons, Shrewsbury.

Fruit was well represented, good quality prevailing all round. For six bunches of Grapes, any colour, first, Mr. Goodacre, Elvaston, with Lady Downe's, Gros Colman and Gros Maroc, two bunches of each. Second, J. F. Campbell, Esq., Uttoxeter (gardener, Mr. J. Hollingsworth), with Lady Downe's and Alicante, two bunches of each, and one bunch each of Mrs. Pince and Gros Guillaume. Third, the Earl of Cork, (Mr. W. I. gulden, gardener), with Black Alicante, Lady Downe's, and Muscat of Alexandria, two bunches of each. For three bunches of black Grapes, first, J. F. Campbell, Esq., with two bunches of Black Alicante and one of Lady Downe's well finished and beautifully coloured. Second, Mr. Goodson, Elvaston, with three short compact highly finished bunches of Gros Colman. For three bunches of white Grapes, first, H. C. Curzon, Esq., with superb highly coloured Muscat of Alexandria. There was an extensive display of Apples for competition. For six dishes of kitchen Apples, first, R. H. C. Neville, Esq., Grantham, with Emperor Alexander, Brabant Bellefleur, Stirling Castle, Betty G c on, Mère de Ménage, and Golden Spire. First for six dishes of dessert Apples, Colonel Paulet with Ribston Pippin; Blenheim's; Cox's Orange Pippin; Matchless Pearmain, handsome; The Queen, bright and handsome, and another variety without name.

Some fine Pears were staged. First for eight dishes, Mr. Parker, Impney, amongst them grand Beurré Diels and Glou Morceau, fine Duchesse d'Angoulême, Ne Plus Meuris, Winter Nellis, and extremely fine Gansel's Bergamot. Second, Mr. Goodacre. Messrs. Richard Smith & Co., Worcester, sent, not for competition, a fine display of Apples and Pears remarkable for colour and quality. The Sawbridge-worth lot contained some very fine Pears and Apples, amongst the latter a fine dish of the handsome Melon Apple, Lane's Prince Albert, the pretty Pigeon table Apple, and King of Tomkins County, Buckingham, and Schoolmaster. Mr. J. Hodges, King's Heath, Birmingham, staged four excellent dishes of Tomatoes, including Golden Queen. Honorary exhibits were an attractive feature of the Exhibition. Messrs. Pope and Sons contributed a bright group of winter blooming Zonals, amongst them Le Bruet, with very large truss, and Souvenir de Mirande, bright cerise pink, with light centre, and very beautiful, were prominent; also a very beautiful erect cross, with flowers on all sides and a handsome base of Ivy; also a stand of fancy Pansies. Messrs. Vertegans and Co. contributed a group of Cyclamens, President Cleveland Bouvardia, Poinsettias, &c., and a fine memorial cross. Messrs. Thomson & Co. had a very artistic group, in which were specimens of *Nephrolepis rufescens triplinatifida*, handsome examples of *Celosia plumosa pyramidalis*, a group of the pretty *Primula floribunda*, Crotons, Selaginellas, and a charming centre of *Plumbago rosca*, Asparagus, variegated Eulalias, Tuberoses, &c.; also a handsome chaplet of flowers for funeral use. Messrs. Hewitt & Co., nurserymen, Solihull, had a nice batch of Zonal Pelargoniums and an excellent display of Cyclamens, a beautiful lot of Bouvardias, *Primula obconica*, and other plants. Mr. F. Denning, florist, also had a fine batch of Cyclamens,

in which whites predominated. Messrs. Sutton & Sons, Reading, sent a collection of thirty leading varieties of Potatoes, many of the samples being very fine indeed, amongst them Abundance, Reading Russet, Nonesuch, Prizetaker, Sutton's Early Regent, Satisfaction, Matchless, and some fine looking seedlings not yet sent out. Mr. Lambert, gardener to Colonel Wingfield, was first for a collection of vegetables in his usual style.

Three blooms of John Lambert incurred Chrysanthemum, a sport from Lord Alcester, were sent by Mr. Lambert, we believe, but the Judges did not consider it to be sufficiently distinct. Notetaking was extremely difficult in consequence of the very crowded state of the hall.

Mr. R. Owen, Maidenhead, showed a large collection of new Chrysanthemums, including many fine novelties.

THE CENTENARY SHOW AT EDINBURGH.—Nov. 22ND AND 23RD.

THE Waverley Market was never better decorated for a flower show than on this occasion, a firm of decorators having done their best to brighten the somewhat dull monotony of the huge building. Competition was encouragingly large—about 800 entries—and the public came in their thousands—10,000 having visited the Show the opening day. The Exhibition was opened by the Lord Provost, when the cup given by the Corporation was presented to the winner. Expenses were very heavy, and the Council of the Scottish Horticultural Association, who got up the Exhibition, carried the mercantile spirit to the extreme, chairs being charged for, and the names of exhibitors could only be found by consulting an official catalogue, for which an enterprising individual provided £30 to the common fund for the right to sell. On the Friday a Conference was held, at which papers were read. On the evening of that day the financial success would appear to have also been secured.

Cut Blooms.—The chief prize was the cup, value £20, offered by the Corporation of the City of Edinburgh (£7, and £3 10s. being added by the Association as second and third prizes) for forty-eight blooms, Japanese, in at least thirty-six varieties. This brought out eight exhibitors, one of whom was unfortunately found to have only thirty-five distinct sorts, and so placed out of the running, though his chances appeared to be very good otherwise. The cup was finally adjudged to those set up by Mr. McHattie, gardener to the Marquis of Lothian, Newbattle, in whose stand were some of the most massive in the Exhibition, particularly fine being Madame C. Audiguier (two blooms), Sunflower (two), Mrs. J. Wright (two), Avalanche (two), Boule d'Or (two), Comtesse de Beauregard, Mrs. F. Jameson, Baronne de Prailly (two), Maggie Mitchell. Very good were Val d'Andorre, Amy Furze, Ed. Molyneux, R. Brocklebank, Meg Merrilies, W. Holmes, Frederick Marrouch, M. J. Laing, Gloriosum, Elaine, La Triomphante (two), Duchess of Albany (Jackson), Mdle. Lacroix, Stanstead Surprise, Madame Baco, Comte de Germiny, Theodora Bullier, Stanstead White, Jeanne Délaux; the others being Hamlet, Hiver Fleuri, Dr. Macary, Buffalo Bill, Lady Lawrence, Triomphe du Nord, Mdle. M. Fabre, Japonais, Soleil Levant, Maiden's Blush, and Criterion. Mr. Parker, Impney, Droitwich, was placed second; and Mr. G. Cockburn, gardener to G. Burden, Esq., Langdale Lodge, Birkenhead, third.

For thirty-six blooms, twenty-four Japanese and twelve incurved, there were also a number of fine boxes staged, the incurved generally wanting in finish, but in this respect better than in former years. This was confined to Scottish growers, a challenge cup and five guineas being the first prize. This was secured by Mr. Milne, Broomknowe. The incurved were full and good, including fine (2) *Empress of India*, Queen of England, Lord Alcester, (2) *Beauty*, Bronze Jardin des Plantes, John Salter, Jeanne d'Arc. Extra—Japanese: (2) Maiden's Blush, (2) Jeanne Délaux, (2) Amy Furze, Triomphe du Nord, Elaine, Etoile de Lyon, Mdme. J. Laing, Dr. Macary, Carew Underwood, Gloriosum, Meg Merrilies, Belle Paule, Baronne de Prailly, Stanstead White, Val d'Andorre, M. Astorg, Peter the Great, Mdle. Lacroix, Florence Percy, and Comtesse de Beauregard. Second, Mr. R. Grossart, gardener to J. Buchanan, Esq., Edinburgh, and third Mr. John Machar, gardener to R. Mudie, Esq., Broughty Ferry. For twenty-four blooms, twelve Japanese and twelve incurved, Mr. G. Burden was first. Incurved, extra fine: Alfred Salter, Golden Empress, Lord Alcester, Queen of England, Miss Haggas, Hero of Stoke Newington, Empress of India, Jardin des Plantes, Jeanne d'Arc, Mrs. Heale, Princess of Wales. The best Japanese were, Stanstead White, Boule d'Or, Japonais, Avalanche, J. Délaux, Meg Merrilies, Mons. Brunet, Sunflower, Madame Baco, S. Owen, and R. Brocklebank. Second, Mr. Matheson, gardener to D. E. Outram, Esq.; third, Mr. D. Forbes, gardener to A. Holt, Esq., Crofton, Aigburth. For twenty-four Japanese, at least eighteen varieties, Mr. Rushton, gardener to R. Tod, Esq., Clerwood, Corstorphine, was first with very fine even blooms; Mr. G. Burden second, and Mr. D. Forbes third. For twenty-four incurved, not less than twelve varieties, Mr. Matheson secured the first place, Mr. J. Short second, and Mr. Watt, Largs, third. Mr. Pirie, gardener to Scott Plumes, Esq., Selkirk, was first for twelve Japanese with fine examples. For twelve incurved, Mr. Q. Geddes, Knock Castle, Largs, was first with a very fine bloom, comprising three Golden Empress, Miss Haggis, H. Shoemith, Lord Alcester, Golden Empress, Prince Alfred, Pink Perfection, Princess of Wales, Lord Wolseley.

The smaller classes were also well filled. Messrs. R. B. Laird & Sons secured first prizes for sixty blooms, twenty-four incurved, twenty-four Japanese, and twelve reflexed (open to nurserymen only) with a good lot. Messrs. Kerr & Son, Roxburgh, second. For thirty blooms the first-named were the only exhibitors. Mr. Morton exhibited some of the

best varieties of Japanese, and from Messrs. Cannell & Sons, Swanley, were a stand of Etoile de Lyon, another of varieties for cutting, and four dozen trusses of Pelargoniums, which attracted a great deal of attention. Messrs. Todd & Co., Maitland Street, exhibited some lovely samples of bouquets, baskets of flowers, &c., and a number of stalls occupied one side of the market where trade could be done in various articles.

Plants.—These were generally below the average quality, the best being those with which Mr. Calder, Calder Bank, Trinity, secured the first prize for four plants Japanese, and four of large flowering sorts. They were grown naturally and with large blooms, Madame de Sevin and Mons. W. Holmes being specially noteworthy. The same exhibitor staged a good example of E. Molyneux and of Criterion in the amateurs' section for two plants. The plants with which Mr. Carruthers, Hillwood, secured the first prize for three incurved sorts were also very fine, these being Mrs. Rundle, G. Glenly, and Mrs. Dixon. Pompons were generally poor. For a group 15 feet in diameter Mr. Grossart was easily first, the second prize lot being especially stiff. Messrs. Jas. Dickson and Sons, Hanover Street, secured prizes for Coniferae and for hardy plants in pots, and for Primulas and kindred plants there was a good competition. Messrs. F. Methven & Sons, Princess Street, contributed largely to the adornment of the building, a fine group of large flowered and Japanese Chrysanthemums with Roman Hyacinths, brightening one of the darkest corners, while in other parts were groups of Conifers.

Fruit.—There was a good show of Grapes, Pears, and Apples—many hundreds of dishes. Mr. Murray, gardener to J. Learmont, Esq., Polmont, secured the first prize for six bunches of Grapes, Gros Colman, Muscat of Alexandria, Lady Downe's, and Alicante being very good. Mr. Murray, gardener to the Marquis of Ailsa, Culzean, second. For three bunches, Mr. J. Leslie, gardener to A. Coates, Esq., Pitculen House, Perth, was first with beautiful examples of Gros Colman, Alicante, and Muscat. Mr. Murray, Polmont, second. Mr. McHattie had the best two and the best single bunch of Muscat of Alexandria, both fine. Mr. Bell, Clive House, Alnwick, with a small, well finished cluster, had first prize with Alicante. Mr. Neil, Peel Towers, Ayton, second with a very large, fine bunch. Gros Colman was also well shown, Mr. Murray being first. The best Black Hamburgh received only a second prize. These were from Mr. Murray, Polmont. Mr. Burnett had a commendation for a box of Gros Colman and Lady Downe's, grown as for market purposes. Messrs. Thomson, Clovenfords, also exhibited fine examples of market Grapes along with Apples in variety.

The prizes for Apples brought out a vast show. For the best collection of at least thirty varieties the prize was easily secured by Mr. Woodward, gardener to A. Leigh, Esq., Barham Court, Maidstone, with about 130 dishes of most approved varieties. Mr. Waterman, gardener to H. A. Brassey, Esq., Prestonhall, Aylesford, was a good second with about seventy dishes, many of which were equal in quality to the first prize lot. Mr. Brown, Chesters House, Ancrum, third. For eighteen varieties of Apples and six of Pears, confined to Scottish growers, there was a strong competition, the first place being secured by Mr. A. Wilson, gardener to R. A. Oswald, Esq., Auchincruive, Ayr; Mr. Cairns, The Hirsell, Coldstream, being second. Mr. Woodward secured first prizes for, respectively, six varieties kitchen and six varieties of dessert Apples, and for six varieties of dessert and three of culinary Pears, in each case with fine examples. Apples and Pears were extensively shown by Messrs. G. Bunyard and Co., Maidstone (who won the gold medal), while Mr. Watkins, Hereford, had a small collection, and from Nova Scotia a representative collection was exhibited. Market growers also showed Apples, and at least one "shop" collection was set up.

Vegetables were fairly numerous, the best collection, which contained good Leeks, Celery, Brussels Sprouts, Cauliflowers, Tomatoes and Onions being set up by Mr. G. Potter, gardener to Mrs. Laidlay, Seaclyffe, North Berwick; the best market grower's collection being staged by Mr. Milne, Sunny Park, Leith. Cauliflowers, Leeks, Celery, Tomatoes, and Potatoes were also well shown.

FRUIT FORCING.

PEACHES AND NECTARINES.—*Earliest House.*—When the buds commence swelling maintain a temperature of 40° to 45° at night, and 50° to 55° by day, admitting air moderately at the latter figure, allowing the temperature to rise to 65° from sun heat, syringing the trees and every available surface morning and afternoon until the blossom buds are showing colour, after which syringing the trees should be discontinued. There must be no attempt at a close atmosphere, but allow a little air at the top of the house to lessen the condensation of moisture by the glass. The inside border will require to be well supplied with moisture. Trees that have been forced previously and are not unduly vigorous may have a good supply of liquid manure slightly warmer than the atmosphere. Borders inside require careful watering, making sure that every part of the soil is thoroughly moistened. Outside borders

will be benefited by lights or shutters in addition to a covering of bracken or litter for throwing off heavy rains or snow.

Houses to Afford Ripe Fruit in May or Early June.—The house should be closed early in December, but no fire heat employed except to exclude frost, and for an hour or two in the early part of the day, if the weather be severe, not, however, exceeding 50° by fire heat in the daytime, syringing the trees and every available surface morning and afternoon. A ridge of thoroughly sweetened manure and leaves placed in the house after the border is well moistened will afford a genial atmosphere superior to that obtained from hot-water pipes, admitting air whenever the weather permits, Peaches delighting in a well-sweetened atmosphere.

Succession Houses.—Push forward the pruning, thoroughly cleansing the glass and woodwork, whitewashing the walls, and dressing the trees for the destruction of insects. Secure the trees to the trellis, top-dress the borders, and keep the house cool by ventilating abundantly in mild weather. If the roof lights are moveable and off, by all means let them remain so until the time arrives for starting the trees. No frost will injure the wood if it be ripe, and if not ripe satisfactory crops are not obtainable.

PINES.—*Young Stock.*—Well ventilated span or three-quarter span-roofed pits or small houses are the most suitable for small plants, which at this season often suffer irreparable injury from being kept too close and warm. At night 65° should not be exceeded, but a mean between that and 55° at night, which, with 65° in the daytime, will be suitable, admitting a little air at the top of the house at 65°, but not to lower the temperature below that point, and when the sun raises the temperature to 75° a free circulation of air should be allowed. Keep the bottom heat steady at 80°, avoiding anything approaching to a damp atmosphere; moderate humidity will suffice. Apply water only when the plants become dry, and then give weak liquid manure. Keep the plants near the glass, and allow them plenty of room.

Suckers.—Those ready for starting now should be kept until March, and if there is likely to be a scarcity of suckers, any recently potted may be retained in 5-inch pots, affording them a light position in a moist pit, with a slight bottom heat and a temperature of 55° at night, keeping them rather dry at the roots.

Fruiters.—In this department 65° will be ample at night, 5° lower in the morning in cold weather, 70° to 75° by day being maintained artificially. Take every opportunity of collecting leaves whilst dry, Oak and Beech being the best, and whenever a favourable opportunity offers push forward whatever may be necessary in the renewal or augmenting the fermenting beds.

KITCHEN GARDEN.

COMPLAINTS are frequent of a deficiency of hands in many gardens, and where this is so a close study of the arrangements of labour will facilitate matters wonderfully.

VEGETABLES IN FRAMES.—Now is the time these are most difficult to preserve from damp. They do not require much water at the roots, and they keep much better when a little too dry than when too wet. Abundance of air should be admitted on every favourable opportunity, and on fine days, especially when the sun is out, the lights should be drawn off. When it is necessary to water them apply it early on such days.

HOTBEDS.—These will soon be in great demand where midwinter and early spring forcing is practised. Pits and frames heated with hot water are the best for forcing, but where these are not available the hotbed will be found most useful, but the amount of service to be secured from it will depend on the manner it is formed. Suitable manure and leaves should be mixed about a fortnight before the bed is wanted, and turned over every other day until the violent heat and steam have escaped. When the bed is finally formed and made firm it will not subside much, and the heat will be steady and lasting. We have just filled a three-light frame on such a bed with Rhubarb roots, which will give a good return in about four weeks. If a number of Seakale roots are lifted, placed in 10-inch pots as close as they will stand, and plunged up to the rim, good produce will be afforded; but it must be grown in the dark to be tender.

DEAD LEAVES ON WINTER GREENS.—There are now many withered leaves on Brussels Sprouts, Savoys, and other winter greens. When these leaves are allowed to remain and decay slugs and snails find congenial quarters under them, and the uncleaned quarters are always worse to deal with in spring than those which have had a little attention as suggested.

WINTER SPINACH.—This is one of the most useful winter vegetables. The September-sown seed has produced luxuriant plants, and in gathering the leaves the largest should be taken first, as should sharp frost occur these will shrivel considerably, and may become unfit for use. The removal of the largest also allows the younger and more central leaves to become hardy, which is an advantage in December and onwards.

PARSLEY.—So far this is abundant, but a severe frost would cause it to decrease rapidly, and in cold districts provision should be made to over it. If frames and lights are disengaged put them over some of best of the Parsley. Hoops may also be placed over the rows to support mats or canvas during the time of frost and snow. We have tried to force Parsley when scarce, but the result was not satisfactory, and it is much better to preserve the crop in time than allow it to be partially destroyed.

Apply lime or manure and rough dig vacant quarters. Where

Cauliflower or Broccoli are apt to have their heads injured by frost cut them when small and store in a cool place. By removing the leaves from the heads and inserting the stems in moist sand they will retain their freshness for three weeks. Place a quantity of long littery manure around the neck of Globe Artichoke plants, as if unprotected when caught by frost they will be crippled so much as to interfere with their success next season.

THE BEE-KEEPER

QUEEN REARING IN RELATION TO HYBERNATION AND WINTER DYSENTERY.

ON May 16th, 1889, page 407, I touched on this subject, but for want of time I could not do full justice to it, and I promised to deal with it as soon as I could. The article was reprinted across the Atlantic, and caused some stir in America. Mr. James Heddon, whom I quoted as being the champion of the pollen theory, had a laugh at me, saying that he reared nearly all his queens by the "natural (?) method in full colonies under the swarming instinct," and implied that I did not know what I was writing about. This is his mode of rearing queens: He lets the stocks swarm, then he places the swarms in a new hive, and sets it on the stand of the old stock so as to get more than a fair share of the bees from the old stock. This is placed behind the swarm with the entrance facing the opposite way. He then daily moves it round until at the week end the entrances of both hives are one way and close together. When the bees are at full work he takes the old stock away to a fresh stand, so that all the bees which are out in the fields and those that are working fly to the old stand, and, not finding it, unite with the swarm. The result is that the old stock is so depleted of bees they at once lose the desire to swarm a second time, and the first queen that hatches destroys the rest. This is known as Heddon's system of preventing after-swarms, but let us consider the result.

The first swarm comes off and leaves but few bees behind to create sufficient heat to develop the queen cells, and as more hatches he further reduces their number until the most critical moment arrives, when he "riddles" the hive of all the bees capable of creating any heat at all. Then the most forward cell hatches out, and this weak and worthless queen tears down all the other cells, becoming the mother of the hive. When cold weather sets in her bees are so constitutionally weak they cannot digest their food, and because he finds undigested grains of pollen he at once concludes that pollen alone is the cause of winter dysentery. Neither Heddon nor anyone else has ever hinted that the digestive organs of the bees were at fault.

The Rev. W. F. Clarke had noticed that if bees went to sleep, which he called "hybernation," they would winter all right, no matter how much pollen there might be in the hives; but he does not appear to have suspected that the manner in which queens are reared had anything to do with the matter, which he admits to be the case in the *Canadian Bee Journal*; nor does he seem to be quite certain that bees are as capable of hibernating as wasps, &c. The greatest opponent to Clarke's theory was Professor Cook, who is the author of a standard book on bees in America, and is looked upon as an authority on all entomological subjects. This gentleman very dogmatically asserted that "bees never hibernate," and stood on his "authority pedestal" as the foundation for his assertion; but as a witness is always cross-examined for the purpose of testing his credibility it is only fair to see if Cook is so good an authority as he would have us believe; hence I will quote from an article of his in the *American Bee Journal* for November 19th, 1884, page 748, which is on the Common Bumble Bees. He says this, "When the first bees come forth in the spring from extemporised cells, caused by eating holes in the pollen, the bees wax these cells and so form honey cells." As a matter of fact none of the bumble bees make "wax" or use it. They mix a paste of

honey and pollen, in which eggs are deposited, then the larvæ eat it, and when full grown they form a cocoon round themselves just where they may happen to be, which makes the combs resemble a bunch of Grapes. When the bees hatch out these vacated cocoons are used for storing honey just as they are. Before any are vacated, or if they are deprived of them, they construct cells for honey of pollen, but never of wax, as they are incapable of secreting it, these cells being afterwards eaten up by the brood. Thus it will be easy to gauge whether Professor A. J. Cook "kens all about bees."—A HALLAMSHIRE BEE-KEEPER.

(To be continued.)

EBOR BEE-KEEPERS' ASSOCIATION.

THE first annual Honey Fair and Exhibition of Honey for prizes of the Ebor Bee-keepers' Association was held by special arrangement in conjunction with the York Chrysanthemum Show, in the Fine Art Exhibition Building, York, on November 20th, 21st, and 22nd. The exhibits of comb and extracted honey were both numerous and excellent in quality. The schedule was divided into five classes, for which there were thirty-three entries. All the exhibits, without exception, were well got up. Those in every way worthy of special mention are—Mr. J. Yorke's twelve bottles of extracted honey, Mr. C. Atkinson's large collection of clover honey in bottles and sections, Mr. J. Davis's and Mrs. Kirk's heather honey in sections, and Mr. Marshall's extracted heather honey in bottles exhibited in his collection. During the three days of the Honey Fair about half the exhibits were sold. To add to the interest of the occasion a choice selection of frame hives and bee appliances was provided for inspection at the Honey Fair by the proprietor of the York and District Bee Appliance Stores and Honey Depôt, A. C. Jameson, who acts as Consulting Secretary and expert to the Association, and into whose hands was entrusted the management of the Honey Fair. Mr. W. Dixon, Belmont House, Beckett Street, Leeds, acted as Judge, and it is only fair to say that he was most careful and painstaking in making his awards.

The following is the prize list:—Class 1, for the best twelve 1 lb. glass jars or bottles of run or extracted honey—First, Mr. J. Yorke, Church Fenton, near Leeds, 10s.; second, Mr. C. Atkinson, Lockwith, York, 5s.; third, Mr. J. Marshall, Buckthorpe, 2s. 6d.; 4th, Mr. W. Richardson, Copmanthorpe, York; 5th, Mr. T. Shaw, Fulford, York.

Class 2, for the best six 1 lb. glass jars or bottles of run or extracted honey—First, Mr. C. Atkinson, Tockwith, York 5s.; second, Mr. W. Richardson, Copmanthorpe, 2s. 6d.; third, Mr. T. Shaw, Fulford, 1s. 6d.; 4th, Mr. J. Davis, Fulford; 5th, Mr. J. W. Richardson, Sheriff Hutton.

Class 3, for the best six 1 lb. sections of comb honey.—First, Mr. J. Shaw, Fulford, 7s. 6d.; second, Mr. C. Atkinson, Tockwith, 3s. 6d.; third, Mr. J. Davis, Fulford, 2s.; equal third, Mrs. Kirk, Stillington; 5th, Mr. W. Richardson, Copmanthorpe; 6th, Mr. J. Marshall, Buckthorpe.

Class 4, for the best and neatest exhibition of honey from one apiary.—First, Mr. C. Atkinson, Tockwith, 10s.; second, Mr. J. Marshall, Buckthorpe, 5s.; third, Mr. F. Baron, Askham Bryan, 2s. 6d.; 4th, Mrs. Kirk, Stillington.

Class 5, heather honey in bottles and sections.—Extra prizes awarded to Mr. J. Davis, Fulford; Mrs. Kirk, Stillington; Mr. O. Atkinson, Pateley Bridge.

TO CORRESPONDENTS

* * All correspondence should be directed either to "THE EDITOR" or to "THE PUBLISHER." Letters addressed to Dr. Hogg or members of the staff often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post, and we do not undertake to return rejected communications.

Bullfinches (J. T. E.).—Since requesting information from Mr. Hiam on his method of taking bullfinches you will probably have seen his communication on the subject (page 443) last week.

Chiswick Hybrid Tomato (Tomato Grower).—We are unable to inform you whether seed of this variety is ready for distribution or not. You can gain information on the subject by writing to Mr. A. F. Barron, R.H.S. Gardens, Chiswick, London, W.

Chrysanthemum Shows (G. N.).—We are obliged by your letter. In reporting shows endeavour is made to represent their general character, and specify the exhibits in the chief classes. It is wholly impossible to publish complete prize lists, however good the exhibits may be in several local or minor classes. For this reason cuttings from newspapers, which mainly consist of a long list of names, though we appreciate the kindness of the senders of them, are rarely serviceable.

Chrysanthemums at Chilwell (W. G. F.).—If you refer to page 417, our issue of the 14th inst., you will find that the extensive display in question has not passed unnoticed, and in any event what you send could not be published through the mistake you have made in writing on both sides of the paper. As a first attempt at writing for the press your communication is fairly good, but you will find that practice is requisite for placing you on a level with the best contributors to garden literature.

Artificial Manure for Fruit Trees (Manure).—The various artificial manures advertised are all good for fruit trees, as we have proved by experience. Thomson's Vine, Beeson's, Clay's, &c., with fish, native guano, and blood manures, may be mentioned as peculiarly suited to fruit trees. You could, not, however, have anything better than superphosphate and muriate of potash; 3 to 5 cwt. per acre of the former, and 1½ cwt. of the latter is a suitable quantity, and should be applied the first suitable weather after the middle of February.

Peach Tree for a Late House (G. H.).—If you want a variety to precede Sea Eagle, Late Admirable, and Lord Palmerston, you could not have a better than Barrington. As, however, Dr. Hogg, Royal George, and Bellegarde are objected to, it is probable that Barrington, though later, may also not be appreciated, as it is of the same character as those not desired; you may add Gladstone. Perhaps Princess of Wales would suit. It is earlier than Gladstone, very large and handsome; but of the two we should select the latter—viz., Gladstone. Prince of Wales has a bad constitution, and is similar to Barrington.

Roses for Wire Trellis in the Open, &c. (F. J.).—We presume you require varieties that are good for cutting, which the following have proved to be:—Climbing Pride of Waltham, salmon pink; Climbing Hippolyte Jamain, rose carmine; Climbing Jules Margottin, carmine; Climbing Captain Christy, flesh; Climbing Victor Verdier, carmine rose; and Gloire de Dijon. You could not select a worse time to move the Daffodils and Narcissus than when the growth is just showing above ground. Mark the roots, and lift them directly the foliage has died, or as soon afterwards as practicable, replanting with little delay. Clematis Jackmani will do fairly well on a north-easterly aspect.

Exhibiting Apples (G. D. C.).—You should have sent us a schedule, and we should perhaps have found something more having a bearing on the case than the three words you quote. Taking them alone we doubt if you could disqualify anyone for staging more than one dish, though the exhibitor could only be awarded the prize for the one the judges considered the best. If your Committee require one dish only from an exhibitor in the class it should be so stated in the schedule. Exhibitors ought not to be left in doubt on these matters. It is quite common to see more than one dish placed in competition by an exhibitor in such a class as you indicate, and under many schedules they are admissible. We have not seen yours.

Caterpillar in Apple Wood (F. J., Kettering).—The insect sent is the caterpillar of the Leopard moth (*Zeuzera aesculi*), which often burrows freely in the trunks and branches of a variety of trees. It is fond of the Pear, Plum, and Apple, and lives two years in the larval condition. Though some instances have been adduced to show that fruit trees attacked by this caterpillar occasionally bear more fruit than those that are uninjured, the final result is sure to be hurtful to the tree. The caterpillars may be killed or extracted from a tree by inserting bent wires in the holes, when these are of sufficient size, or if it be discovered while these are small a solution of soap or tobacco water may be thrown up by means of a syringe with a fine nozzle.

Repotting Vallota (F. G.).—The above, we presume, is the plant to which you refer. It will be best left undisturbed till spring, only giving sufficient water to keep the leaves fresh through the winter, an excess of moisture at the roots being injurious. If fresh soil is needed it may be given in the spring just when fresh growth commences. Good drainage is essential, and a mixture of turfy loam with a little leaf soil and crushed charcoal will be suitable. Press it down firmly in a pot only large enough for holding the roots comfortably, overpotting not being conducive to healthy growth and floriferousness. Some of the finest plants we know have remained in the same pots for five years. The plants require heat, moisture, and abundance of sun in summer for making free early growth, with a reduction in moisture during late summer for ripening that growth for flowering in the autumn.

Vines Infested with Mealy Bug (T.).—Cut all the Grapes with a piece of wood, and place in bottles of clear rain water with a few bits of charcoal in each, and keep in a cool dry place, placing the bottles in a slanting position so that the bunches hang clear of the bottles. They will keep quite as well in this way as on the Vines, and the latter will be clear for operating against the mealy bug. Get some cans full of rain water, those holding 3 gallons are best, and to every 3-gallon potful add a wineglassful of petroleum, and with this syringe the Vines thoroughly, wetting every part of the foliage, the rods, and woodwork of the house. Repeat in the course of four days, and again so soon as the leaves have fallen, which, as they drop, must be cleared

away and burned. It is necessary that the petroleum be kept thoroughly mixed with the water whilst it is being applied, which may be done by one person stirring sharply with a broom handle, whilst another person applies it to the Vines; or, if only one person performs the work, first fill the syringe and squirt a few times sharply into the watering-pot, and afterwards apply alternate squirts to the Vines and into the watering-pot. When the leaves are all off prune, and, removing the loose bark, wash the Vines with soapy water at 120° to 140°, employing 8 ozs. of soft soap to a gallon of water, and paint the whole of the woodwork of the house with petroleum, moving the plants out of the way; limewash the walls, and dress the Vines with some approved insecticide.

Names of Fruits.—The names and addresses of senders of fruit to be named must in all cases be enclosed with the specimens, whether letters referring to the fruit are sent by post or not. The names are not necessarily required for publication, initials sufficing for that. Only six specimens can be named at once, and any beyond that number cannot be preserved. (G. S.).—The Pear is probably Comte de Lamy.

Bees Fanning (A Young Beginner).—There is nothing extraordinary in the bees fanning during exceptionally fine weather. Bees were not only carrying much pollen, but sometimes a little honey. Our own bees have been fanning a good deal lately, arising from their good condition, and from what is stated above. In addition to that, bees fan when queenless. As yours carry much pollen it does not indicate that; still, it is not a true criterion to judge by. They act similarly when the queen is unfertilised, and also at a certain stage when foul brood is present. You give no information about the odour from the hive, whether it be sweet or offensive; if the latter you may be sure something is wrong, and if on examination there be sealed and unhatched brood cells, the contents of which are of a brown colour and of a gluey nature, transfer the bees to a clean hive, and after forty-eight hours transfer again into another full of clean combs. As you are a beginner, however, you may not have these at hand; if so wait till say February, turn the bees into an empty hive, then after forty-eight hours into one filled with comb foundation and feed them. The pigstyes can have no ill effect on bees, but the hive should be covered somewhat in addition to outside case. You do not say what time has elapsed since the bees were brought home. Nothing excites foul brood so readily as overheating, and had the same pains been taken to initiate beginners with that fact, instead of assumptive evidence of certain cures, we would not be hearing so much of the plague.

COVENT GARDEN MARKET.—NOVEMBER 27TH.

MARKET very quiet, with good supplies. Prices unaltered.

THE FLOCK IN WINTER.

LAMBING TIME.

"LUCK in lambing!" Yes, this is the term so frequently heard among shepherds and farmers, and whenever we hear it we feel tempted to ask, What has luck to do with it? For we certainly cannot agree with the popular but fallacious idea that a certain per-centage of loss of ewes in lambing is inevitable. The flock of the home farmer should consist of choice ewes, home bred, within age, and selected with due care and judgment, and in such a flock under good management a loss is quite exceptional. But if the flock is made up with ewes of all ages, with a large proportion of full-mouthed ewes, or, as is so often the case, with a good many over-age, then there is a proportionate increase in the risk of losses.

So much depends upon the shepherd; aye! and upon the shepherd's master too. A lazy shepherd will often harrass the sheep by a too free use of his dog, and quiet gentle treatment is of especial importance. We have pointed out the evils attendant upon folding ewes upon Turnips now, and we would again urge the importance of shelter, quiet, and judicious feeding. The sheep will soon show us how much they appreciate shelter if we only give them an opportunity of doing so. Turn them out on a bleak plain on a cold wet night, and if there is any possibility of shelter from tree belts they will take full advantage of it. Often have we in these articles recommended the erection of open sheep lodges for shelter on pasture, because we know the outlay to be a sound investment, tending, as it does, to preserve the sheep from harm. Can any reasonable person see ewes in the wretched plight they are so frequently in during the present month—drenched by cold pelting showers while standing in a sea of mud—suppose it possible for them to continue healthy, or, at any rate, to pass through the strain of such exposure without suffering? What is the result of such ill treatment but that heavy loss of ewes and lambs which is attributed to bad luck? Let there be an end of such stupidity, and let sheep have the shelter they require equally with all other animals of the farm.

As the lambing begins the ewes are brought close to the fold or lambing yard, and we always hold the pasture near the fold in reserve for this purpose. Each ewe with its progeny to a separate pen, in order that it may not only have shelter, but be sufficiently under the shepherd's eye for him to see if all is well, or if any special treatment is required. The lamb may not suck aright, the ewe may not "take to it" as she ought, she may be deficient in milk, and the lamb may require aid from the shepherd's milk bottle. Each case must be treated upon its merits, strong ewes and lambs being turned out of the pen after a few hours, others requiring special care being kept there just so long as is necessary.

There should always be enough space in the fold to take in the

entire flock without crowding. The earliest lambs with the dams are out upon open pasture upon all fine days, but there must be no risk run by exposure on very cold days or nights. One can hardly understand the folly which suffers lambs to be exposed to weather which is likely to hurt them, yet it is a most common thing to hear of losses arising from such carelessness.

If the flock has the taint of foot rot every case must be taken in hand at once, and persistently. It is lamentable to see the lambs suffering from this infectious disease, for they then soon fall off in condition. A judicious master will see his interest in allowing ample help to the shepherd at this critical time, and not press so much work upon him that negligence in something or other is inevitable. Keep the shepherd with his flock, and let roots, fodder, and all other things required be taken to him regularly, and then insist upon full attention being given by him to every animal under his charge. When a flock goes wrong the shepherd is blamed, but depend upon it his master is also in fault. Self interest or the sense of duty should suffice to bring every fault or falling off under the master's eye before the evil has become serious; but when one sees ewes lame by the dozen, with many of the lambs limping too, it may be taken as a sure sign of carelessness that is quite inexcusable.

WORK ON THE HOME FARM.

With a continuance of such fine mild open weather all work on the land should be finished as speedily as possible, not a day being taken for any other purpose. To glance at sound practice, all land was ploughed as the stubbles became clear, and dropped corn eaten by sheep, pigs, or turkeys. On heavy land we began autumn sowing immediately after harvest, or rather when the first stubbles were cleared. First came *Trifolium incarnatum*, then Rye, followed closely by winter Oats, Tares, Beans, and Wheat. With such work well in hand Mangolds and Swedes were got up, carted and clamped as growth ceased. We never had better weather for clearing the roots. The crop was exceptionally heavy, but the land was so dry and firm that carting was comparatively an easy business, one horse doing work that requires two in a wet season. So far all went well, but a wet October caused a temporary cessation of such work, and there was the usual outcry from laggards about arrears of work, very little land ploughed, no sowing done, and only part of the roots cleared. But do not let us forget that these are the men who make such an outcry about hard times.

We do not like to be hasty in bringing corn samples on the market, and Barley especially may be threshed at a loss. It is now well out of the sweat which occurs in every Barley stack, and threshing is being done gradually so as not to overfill the cleaning floor. There is considerable difference in the way in which various threshing machines screen corn, and all good malting Barley should be screened once or twice after it is threshed. In selling Barley colour stands first, next comes condition, substance, and purity of sample, freedom from tail corn, and any discoloured grain. Every point tells, and we know no better investment than the purchase of a thoroughly good new corn screen, through which we frequently pass Barley twice, if it appears worth the labour involved in doing so, thorough screening often making a difference of several shillings per quarter in the price. We lay particular stress upon screening Barley, but the plan answers for all corn that is well grown and well harvested. High-class malting Barley is comparatively scarce, and the best samples command special prices altogether above ordinary quotations. The yield per acre is low, the average being very little above 26 bushels per acre, and there are crops so poor that they will not realise anything like the expense of cultivation.

REMARKS.

17th.—Wet mist nearly all day. 18th.—High fog early, dull day. 19th.—Cloudy, but dry. 20th.—High fog or smoke cloud rendering gas necessary, except for a few hours at mid day. 21st.—Dull and dark. 22nd.—Dull and mild. 23rd.—Dull and mild. A very dull week, with high barometer, small daily range, and scarcely a gleam of sun. The rain on the 23rd was the first since the 3rd, the fall on the 16th being merely the product of wet fog.—G. J. SYMONS.

LESSONS OF THE SHOW SEASON.

DURING the past month Chrysanthemum shows have occupied a large share of horticultural attention, and a proportionate space in gardening periodicals has been devoted to the records of proceedings; the rush is now over, and with the exception of a few annual meetings, the horticultural season of special activity may be considered as ended. This is a good opportunity to look back and see what has been accomplished, what fresh ideas have been carried into practice, what lessons have been learned, in fine, to judge the practical results of time employed and the energy expended. A very cursory review gives much that is noteworthy and satisfactory, encouraging to those who have been engaged in the work in any capacity, and gratifying to the interested onlookers, who may have contributed to the funds utilised in the promotion of a healthful competition. I have for some years had ample opportunities of judging the results of shows generally, and these autumn exhibitions will compare most favourably with any others in their usefulness and importance. They have been largely the means of extending and improving the culture of a plant that is invaluable in all respects owing to the season at which it flowers and its adaptability for decorative purposes, and in this alone they have performed a service of no mean importance. Beyond that, however, they have afforded opportunities for meetings amongst gardeners at a most convenient time, the interchange of ideas, mutual assistance in the solution of difficulties, and the general advantage that invariably arises from the association of men concerned in one occupation. The stimulus, too, induced by the competition at such meetings has a beneficial effect, encouraging greater efforts in what happily is almost invariably a generous rivalry, and producing effects far beyond their immediate cause. It certainly cannot be said that all the best gardeners are exhibitors as some are prevented by various reasons from entering the lists; but amongst the successful exhibitors in specialties like the Chrysanthemum will be found a large proportion of thoroughly competent all-round practitioners, their achievements in one department being merely indications of their general skill. This opinion is founded upon years of observation and a wide circle of gardening friends in all parts of the country. Plenty of examples could be given in proof of the statement, but it would be invidious to signalise a few amongst so many of equal merit.

There are several other matters in connection with these shows requiring a little attention, that may be regarded as "lessons of the season," and the first to which we may devote a little consideration is the grouping of Chrysanthemums or arrangement for effect. In thousands of conservatories throughout November and a part of December the chief portion of the floral display is formed by Chrysanthemums, and in their disposal to produce the most pleasing results considerable diversity of taste prevails. The most common way is to place the plants in a semicircular block, the shortest in front and the tallest at the back to form a sloping bank, the arrangement of colour and the quality of the blooms being relied upon for the desired effect. This plan is generally carried out at shows, and it must be admitted that rich and telling groups are so produced; still from an artistic point of view they are commonly unsatisfactory, formal, heavy, and monotonous. Farther, when the marginal plants are not sufficiently dwarf or well clothed with foliage the spectator has a dreadful array of pots, bare stems,

and stakes presented to his view, certainly not calculated to awaken his admiration. A knowledge of these defects has led the committees of several societies to permit the introduction of foliage plants as a belt to the groups, which in several cases (especially so at Hull) has been found to be a useful addition, but the idea requires to be extended in its operation.

The Brighton summer shows have long been celebrated for their groups of Ferns, and it is evident that some exhibitors in that district possess excellent taste in the arrangement of plants. At the last November Show in the same town attempts were made to introduce a little diversity in the groups of Chrysanthemums, and though only those plants were employed in the principal classes provided in the schedule, the general style was more varied and tasteful than is usually seen at exhibitions, the sloping bank pattern being departed from in several instances with good results. But a non-competing group, contributed by Mr. Miles, the execution of a suggestion by Mr. Mark Longhurst, was a departure from stereotyped methods of arrangement that deserves notice and imitation. The group was only a small one, and on a larger scale the principle could have been more effectively developed, but there was sufficient to show what can be accomplished in arranging Chrysanthemums with other plants. The charming method of grouping miscellaneous plants, adopted with so much success by Mr. W. Brown of Richmond, Mr. Brückhaus of Maida Vale, and Mr. Hudson of Gunnersbury, is familiar to metropolitan horticulturists, a low groundwork being formed of Ferns and similar plants, from which rise graceful Palms, Crotons, Dracænas, and such flowering plants as may be available constituting the chief features. In numerous districts the old formal "banking" style of grouping has become obsolete, mainly in consequence of competition with the more artistic style mentioned. The Brighton group was formed on the same plan. The foundation consisted of Ferns, small foliage plants, &c., with a few taller Palms, and then dwarf light graceful Chrysanthemums were introduced with excellent effect. Comparatively few were employed, but the colours were well selected, Japanese varieties being the most telling, and the result was all that could be desired. A class could be advantageously introduced in many schedules for such groups, and it would permit numbers of gardeners to compete who cannot stage a large collection of Chrysanthemums alone. It would have a tendency to improve the general taste in arrangement, and in any case would be a welcome addition to the other classes where there is plenty of space at command.

Another department of Chrysanthemum shows is rapidly increasing in importance and utility—namely, that devoted to floral decorations. A surprising example of what can be secured in this way was afforded at the National Society's Westminster Exhibition on November 12th and 13th, when, as an experiment, a special class was provided. This, the schedule stated, was "for a table of bouquets, wreaths, sprays, buttonholes, &c., &c., illustrating the decorative purposes to which Chrysanthemum blooms can be applied. Any appropriate foliage may be employed. Each exhibitor restricted to a table space not exceeding 6 feet by 3 feet." The prizes were small in amount, yet there were five exhibits of an exceptionally tasteful character, occupying a space of 30 feet run of table, a result which must have far exceeded the expectations of the projectors. Nothing could have better proved the adaptability of Chrysanthemum blooms for decorative purposes than these contributions, and while they showed what can be done, they also taught what should be avoided, a "lesson" that some of the competitors, as well as many of the visitors, who were specially interested in it, will take to heart.

Several interesting points were illustrated in the competition, and though everyone knows full well the decorative value of Chrysanthemum flowers, yet it is seldom that we see such admirable examples of their tasteful employment as were afforded in the class under notice. One fact attracted attention immediately—namely

that Japanese varieties were almost exclusively used, and of these only the lightest and most distinct in shape and colour. In the best arrangements the first object is to avoid heaviness, and unfortunately the incurved Chrysanthemums, unless very sparingly employed, are very likely to convey the impression of undue weight. A solid, heavy bouquet, basket, or stand is highly unsatisfactory, however well the colours may be harmonised or contrasted. The admission of other foliage is an important gain in this form of decoration, and full advantage was taken of the privilege at Westminster, Adiantum fronds, Ivy sprays, Berberis leaves, &c., being freely used with good effect. To these were also added Grasses in several cases, and in one Orchids were also introduced. This gave rise to some discussion, as it was thought to be contrary to the spirit, if not to the letter, of the schedule conditions. The referee, however, ruled that other flowers could not be excluded in the absence of any express statement to that effect, and further that as the object was to show what could be accomplished with the Chrysanthemum from a decorative point of view, the employment of other flowers was really helping in that direction. It is so obvious, however, that with foliage and Grasses such charming designs can be produced by Chrysanthemums, unaided by other flowers, that it might be desirable to restrict the class to them, specially indicating also what would be required from each exhibitor, so that all would be placed on equal terms, except as regards the material and the mode in which it is utilised.

For stands and baskets Chrysanthemums are well suited. Of the former one of the best I have seen was that which gained Mr. Crane the premier prize at Westminster, a graceful lightness combined with good colour effect being produced. Some of the baskets in the class just referred to were excellent from Messrs. Perkins and Son, who also had a most elegant design of the same character at Rugby. Bouquets of these flowers are commonly very unsatisfactory—crowded, flat, heavy, and altogether graceless productions; yet the Coventry firm with others have shown what can be accomplished, and both at Kingston and Rugby I saw some of these bouquets that were quite equal in taste of design and execution to some of the best bride and ballroom bouquets composed for sale or exhibition by the leading firms. Both Mr. Chard and Mr. Brown have given the public abundant examples of their skill in general floral arrangement, but neither has yet done himself full justice amongst the Chrysanthemums. Perhaps with more encouragement in the shape of prizes we may see them and others induced to exert their best efforts. Mr. Newman has already proved what can be accomplished in this way, and frequently stages bouquets of the best taste. Wreaths vary greatly in their style, but the general faults are unnecessary size and heaviness. Purity of flowers is an important point in wreaths, and the introduction of colours, either in flowers or foliage, requires great care, or the whole is readily marred. For instance, one exhibitor of a well-constructed wreath of white Chrysanthemums sought to improve it by regularly dotting it with brightly coloured Ampelopsis Veitchii leaves, a mistake of which he subsequently became fully conscious.

Dinner tables are frequently adorned with Chrysanthemums at this time of the year, and it is not surprising, therefore, that classes should be provided for this form of decoration. It must be acknowledged, however, that the results are too often disappointing. At Hull some seven or eight large tables thus decorated were arranged, but they were all defective in some particulars. White flowers had been too liberally or exclusively employed in the majority, consequently there was a want of character that under artificial light had a very tame and dull appearance, or, as one expressed it, "They were quite funereal." Others had introduced yellow or bronze varieties, but spoilt their designs by having heavy central stands, altogether too obstructive. Some of the rich golden, bronze, red, and crimson Japanese have a grand effect under gaslight, and if a few white varieties are used judiciously with them delightful effects can be obtained. Two of the best tables in this way I have seen all the season were at St. Neots, where some extremely rich

colour arrangements were produced with a few flowers and varieties without having a miscellaneous assortment of discordant tints.

Respecting the cut blooms in competition, the varieties best represented, and the novelties that have come to the front, a few notes will be contributed on another occasion, when some other "lessons of the season" will be indicated.—LEWIS CASTLE.

KEEPING PEARS.

INSTRUCTIONS in growing Pears to the highest perfection are frequent in these pages, but how to preserve the fruits in the best possible condition after they are gathered until they are fit for the table or market is a subject that is rarely dealt with. It is, however, an important one, and worthy of our best consideration, therefore a few notes on this subject may not be out of place at the present time.

Late Pears that cannot be given special positions on walls in some of the eastern, midland, and all the northern counties do not perhaps attain the same perfection before they are gathered as they would if they could be given more favourable positions, and consequently, shrivel, either partially or wholly, before they are ripe. Many of them shrivel only towards the stem, and although little fault can be found with the flavour generally they are inferior in appearance. That best of all Pears, perhaps, Marie Louise, with us when grown on trees in open quarters always shrinks towards the stem, even in the best of seasons—that is, when given the general treatment accorded Pears after they are gathered. They continue to be green in appearance, and not to assume that rich yellow colour characteristic of those grown on south walls or under glass, and are ripe soon after they are gathered. Open trellis shelves arranged one above another in some room or shed are not suitable for Pears. To colour Pears well and prevent shrivelling they should be stored where they can be kept practically air-tight. The majority of rooms are too airy and too dry, and how to overcome these evils may not have occurred to the majority. At any rate a good number of fruits may be spoiled before the best means of keeping them has been found. The best method of carrying out this work is to have in readiness a good number of boxes made of half-inch boards, boxes that will hold four or five dozen fruits, but larger or smaller boxes may be used. We have some containing no less than thirty dozen, but these are too large. Unless sufficient Pears of one variety are at hand to fill them they give more trouble than would be occasioned by a smaller size. Then, again, when large boxes are filled too many fruits ripen at one time to be of use unless they are required for the market.

The fruit when gathered must be properly dry, and sorted in three sizes—first, second, and third. The two first can be packed alike, and the last as well as all small-growing varieties on a slightly different principle. The lids of the boxes may be fastened with wire secured on the top of the box lid on each side, and then passed through a small wire staple at each side of the box. By this means they are more easily examined than if the lids are nailed down. Nothing surpasses paper shavings for packing Pears in. Hay and straw are too heating, especially if in large boxes. At any rate they are likely to be slightly flavoured with these materials when removed. Place a good layer of shavings at the bottom of the box, and then a layer of fruits each packed in a separate piece of paper. Over these place a layer of paper shavings, then another layer of fruit, and so on until the box is full. Two layers of paper can be placed over the top, the box being full and the lid secured. The variety, time of gathering, and whether first or second size, as well as any other particulars, should be placed on a label and tacked to the lid. This saves considerable trouble afterwards. When it is necessary to fill one box with two varieties, those that ripen about the same time should be selected, and a label placed at each end of the box. The third size and fruits of small growing varieties are packed in the same way, except placing them singly in paper. Over the first layer of shavings a sheet of paper is laid, and then a layer of fruit, another sheet of paper, then shavings, and so on. When all have been stored in boxes they can be arranged in any cool room or shed. Those that ripen first should be placed on the top, or where they can be reached without disturbing the others. The first and principal labour is in making the boxes, but they last for years. Those in the neighbourhood of towns will have no difficulty in procuring suitable boxes, chiefly from grocers and provision dealers, or better still are the boxes in which the French send their Pears. The labour of storing Pears in boxes is considerably more than placing them on shelves, but if the fruit is worth growing well it is also worthy of being stored, so that it can be presented in the best possible condition when ready for use.

Those who have never stored Pears on this principle may upon first examining the contents of the boxes be somewhat alarmed at finding the paper and shavings thoroughly damp, which they are certain to be. Some of the fruits in our large boxes were quite moist the other day. This is one reason why we object to too large boxes. No harm appears, however, to result, although we do not like to see them too moist. The fruits when stored in boxes keep plump and colour beautifully. There are very few Pears that refuse to colour if properly treated.

By this process many varieties colour well while the flesh remains firm, and we are convinced that they are improved in flavour by placing them in a warm room during the last stages of ripening. When the fruit is wanted, or some of it, to maintain a succession it can be placed in a warm room after they have been in boxes about a week or so, according to the variety. *Beurré Rance*, *Bergamotte Esperen*, *Josephine de Malines*, and other late varieties should not be hurried.—WM. BARDNEY.

HARDY PLANT NOTES.

HELLEBORES.—The majority of persons who possess handsome specimens of these plants will be looking forward to the annual display of their welcome flowers, the better forms of which are so justly prized at this season of the year. The thought of attempting to transplant the roots at this time would undoubtedly appear somewhat ridiculous, as no doubt it would be to some extent were it recommended generally; but it is not, nor is there any occasion to disturb these specimens so long as the possessor is certain that they have plenty of suitable soil for their requirements, and the plants themselves by the luxuriance of their foliage and the abundant supply of their flowers afford ample proof that they are in good condition. But what I have to say just now about these very desirable plants is more especially directed to those who may be thinking of making new plantations, and my advice is to plant at once and not delay till the arrival of spring, a season, that suits many of our best hardy plants admirably, but is altogether wrong for the "niger" section of this family, and particularly does this apply to all those localities where the soil is light or sandy, or, what is equally bad, a soil which for summer is overdrained.

Though not particular as to soil itself, these Hellebores are most happy in rather heavy loamy land, the depth of which cannot be too great, and finally a cool moist position where a free circulation of air is continually going on. Some few years since the whole of our Hellebores were planted on one of the open quarters, and though cared for as well as circumstances would permit, their appearance indicated that the position was unsuitable, but better quarters were obtained for them, and they now grow in luxuriance between hedges of Oval-leaved Privet, well repaying by their rapid increase. The full heat of summer sun they cannot endure, nor do they require the incessant cold and shade that a 9-inch wall affords. The shelter and shade they need is only partial, and should be afforded them by evergreen hedges wherever possible. This kind of protection is of great benefit, and in many instances our plants which are nearest the hedge, in spite of the latter robbing the soil by its mass of roots, as well as keeping off the rain, are decidedly more vigorous and the foliage more abundant than are those plants 5 feet away, and which have in consequence a far greater share of summer sun than those nestling at the foot of the hedge.

From these facts, then, it may be gleaned that a partially shaded spot is what they thoroughly enjoy, and such a one could, if sought after, be found in almost any garden; for a couple or three shrubs or Conifers would supply the need if properly placed, and what more beautiful or useful than large handsome patches of these old-fashioned perennials? Not only does the foliage appreciate protection from sun and heat, for the roots also are equally fond of moisture, or, more correctly, of being continually cool, to ensure which some amateur growers bury blocks of sandstone in the soil. But while admitting the great benefits accruing from such treatment, I fear it is too elaborate for the majority of those who grow Christmas Roses. Three feet depth of well enriched soil they fully value, and for dry, hot, much drained soils, cow manure may be employed freely, keeping it a few inches below the roots at planting time. No period is equal to the early autumn months for planting, and the earlier the better, thereby insuring as many newly formed roots as possible. When well established, these plants are much benefited by bountiful supplies of liquid manure in autumn and winter. I much prefer giving it to them at this time when the soil generally is well charged with moisture, for then it lies about the surface and descends gradually to the roots below; while, if given in summer time, it quickly passes through the soil, and affords little or no help to the plants themselves. It is worthy of note that the varieties of *Helleborus orientalis*, as also *H. colchicus*, *H. anti-*

quorum, *H. guttatus*, and *H. purpurascens*, do not suffer in the same degree either from the effects of sun or from spring planting as the varieties of Christmas Rose, and may therefore be planted in more open positions, and over a more extended period, without incurring any risk. Many of this last-named section have very handsome foliage, which, coupled with their more or less beautiful and curious flowers, are always productive of good effect in the herbaceous border, the rockery, or the shrubbery.

HERBACEOUS PÆONIES.—These afford another illustration wherein autumn planting is essential to success, and all who desire the best results should make a point of early autumn planting for all Pæonies. More especially should this fact be impressed upon all who take an interest in these plants, for the reason that they take longer to establish than any other hardy perennials. Those which have made 6 or 8 inches of young growth are often planted, but alas! for the results, for not only is that season's growth lost, but the plant is also much weakened, and the ensuing autumn will disclose, if an examination be made, nothing but weak thin looking buds in place of the large plump buds which may have been had autumn planting been resorted to. Few plants are less trouble than these Pæonies when once established, and they may remain for an indefinite period in the same position, and increase in size and beauty annually. A little extra pains with them at planting time is not, therefore, of great moment when it is considered that they are safe for ten or a dozen years without replanting; indeed, I know an instance where a plant of *Triomphe de Paris* has stood for nearly twenty-five years, and every season it is quite a feature, fully 4 feet through, and producing abundance of its lovely fragrant flowers. It is when seen thus that some idea of their value is obtained. All they require is a deep and rich soil. Secure good plants with well developed crown buds, and plant in autumn. All the after attention they require is an annual mulching of manure, or plenty of liquid manure in the autumn and winter. In the event of mulching be careful not to injure the buds, as these show rather prominently above the surface in some kinds even in winter time after they have been planted a couple of years.—J. H. E.

SALT AS A MANURE.

MR. RIVERS need not fear that a moderate dressing of salt will injuriously affect his Plum trees, or, in fact, any other plant. The vegetation of Mount Edgecombe, the sheltered gardens of Falmouth, Penzance, Tresco, in the Scilly Islands, and Jersey, which are protected from the direct action of the saline spray, prove conclusively that a soil containing a large proportion of salt deposited from the saline atmosphere is not injurious to vegetation, but on the contrary, is compatible with the most luxuriant growth.

On the coast line, and for as far inland as the saline atmosphere is carried by the winds, the application of salt would be unnecessary, but further inland the soil may not contain sufficient soda, and perhaps chlorine, for the requirements of some plants. I know no reason why salt (chloride of sodium) should benefit Plum trees, but I cannot speak positively, as I have been unable to find an analysis of either the wood or the foliage; these may contain such a proportion of soda as would show that the application of salt is useful. But, on the other hand, most complete analyses have been made of the fruit; these indicate that potash is the proper manure for Plum trees, for the ash of the fruit contains 59 per cent. of potash and only $\frac{1}{2}$ per cent. of soda, an exceptionally small proportion of that element. All plants contain more or less of soda. The ashes of the fruit of the Apple, Fig, and Strawberry an unusually large proportion, averaging about 27 per cent.; of the Pine and Gooseberry about 10 per cent.; therefore these fruits are benefited by moderate dressings of salt. Asparagus, Beet, Radish, and Rhubarb all contain a very large proportion of soda. Carrot, Lettuce, Parsley, Vegetable Marrow, Hyacinth, and Primula more than an average proportion, consequently salt is indicated as a suitable manure for them. Many other plants might be specified to which salt is useful, but these are sufficient for the purpose of illustration. Overdoses of salt are destructive to vegetation, so are overdoses of guano, the value of which as a manure no one will dispute. Salt by itself in the absence of one or more of the elements necessary for plant growth is useless. Every plant requires certain proportions of potash, soda, lime, magnesia, iron, phosphorus, sulphur, silica, chlorine, and nitrogen; all these must be present in the soil in such proportions as each plant requires for the purpose of perfect growth. Ville has stated that all soils contain sufficient of all of them except potash, lime, phosphorus, and nitrogen, and limits his formulas of artificial manures to these, but Dr. Griffiths has proved conclusively that iron, in the form of the sulphate, may be added to artificial manures with very great advantage to the crops. Others have proved that the manurial value of soda and magnesia is in certain cases very

great, from which it may be fairly concluded that to attain the best results from artificial fertilisers it is desirable to make them as complete as possible, proportioning the ingredients, where we have reliable analyses of the plants or soil, according to the special requirements of the former and the deficiencies of the latter.—EDMUND TONKS.

OUTDOOR PEACH CULTURE.

I HAVE often heard it said that if we want a Peach of first rate flavour it must come from trees grown on the open walls. I believe many others are of that opinion, myself included. Trees grown under glass with special treatment possess one great advantage over those grown outside in more certainty of a crop and perhaps larger fruits; but briskness of flavour as well as colour and firmness of flesh are often wanting, and which even the orchard house, at one time so popular, fails to supply. My object here is not to induce people to ignore growing Peaches under glass, which is a most commendable plan for lengthening the season of production, but I cannot help thinking that outdoor cultivation of Peaches has been too much neglected and in some cases discontinued without sufficient reason. I see no other cause for this apathy than that our fickle climate and short and sometimes sunless seasons militate so much against the certainty of a crop. I hope some day to see a little more attention paid to the old system of Peach growing, and more of our garden walls adorned with this delicious fruit.

There is no lack of good sorts to back up the effort that have stood the test of time, and which to this day may be produced as good and luscious as ever they were. It is only to go about the work in the right way by securing a good rooting medium, favourable aspect, and plenty of wall space, together with plodding attention, patient training, and pruning with sound judgment so as to admit all the light and air to the trees, and beyond all to keep them free from injurious insects and mildew. Beyond this, however, the comparative tenderness of the Peach tree suggests a proper system of protection from spring frosts, for be the situation ever so favourable our climate is too fickle to run the risk of doing without it.

Coming first to the soil most suitable, it may be mentioned that the Peach requires a lighter material than either the Pear or Plum, yet a good sound loam, rather adhesive than light, made up about 2 feet 6 inches in depth, resting upon a good natural drainage if possible, and young trees without the addition of strong manure I have found answer well. The object is to prevent the production of coarse, too luxuriant, or spongy shoots, which the trees are liable to do when young. Neither is it well for the first year to make the border too wide, 4 feet being quite sufficient; rather would I add to the width as the trees require it. Whatever preparation may be made for the roots care should be taken to prevent their getting too deep, not only by the sinking of the soil, but by additions made from time to time as top-dressings. If the borders are cropped it will be necessary to add to the staple of the soil to replace that taken from it by the crops. I think heavy cropping of fruit tree borders a necessary evil, inasmuch as very few gardens are of sufficient scope to dispense with it.

Next to the soil is a suitable aspect and sufficient wall space. With regard to the former, though the south side of a north wall is generally chosen, I have in some gardens both seen Peaches and had them do well on an eastern or western aspect, provided the situation is high, dry, and open, and no light, sun, or air obstructed by other trees. I do not advise Peach trees to be planted alternately with Pears and Plums, as in these cases of mixed planting the Peach trees are the first to succumb. With regard to wall space it is false economy to curtail that too much; if so, the severe pruning necessary to keep the trees within bounds precludes them from ever reaching or growing into a healthy and fruitful state. A fair height to the wall is as much a necessity as the proper distance from tree to tree. Too much cramping either way ends generally in disappointment.

The many examples of skilful outdoor Peach culture to be seen in various gardens give proof, if any were needed, that a judicious system of pruning and training of the shoots is as important to help towards success. Both the Peach and Nectarine bear their fruits upon the young wood of the previous year, and the blossom buds rising close to the eyes of the shoots it becomes evident that the more light, sun, and air they can get the better will the wood be ripened. In that case summer pruning or disbudding at different times, so as to keep the shoots thin and regulated, is more important than winter pruning where the knife has to be used—in fact, the latter implement should be employed very sparingly. Winter pruning, however, is best done when approaching the spring months, when the most severe frosts are past, and before the blossom buds become very prominent. In pruning or disbudding always have an eye to

keeping the body of the tree well supplied with healthy young wood; if not, as the tree extends in size the middle part of it becomes bare of both wood and fruit.—THOS. RECORD.

TREATMENT OF SOILS, MANURES, AND CROPS.

BROCCOLI.

BROCCOLI should not follow any crop of its own family, but, like Cauliflowers and Cabbages, succeed one of the crops previously enumerated. Sow Snow's Winter White or Knight's Protecting Broccoli on a warm border the first week of March. These will come in for cutting in January, February, and March, after the late autumn Cauliflowers. Knight's will often turn in during December, and I have found it very useful. The plot chosen for the seed bed should be good soil, as present manuring is useless, well dug and trodden down firm, and all will be well if protected from the ravages of the birds.

In the early part of May plant out a plot 2 feet asunder on a well trenched and manured open portion of the garden. It is necessary that the ground be hoed deeply often during the summer, so as to admit the air freely to the soil. They can receive a good watering with liquid manure at any time when the soil is dry. It is necessary to lift them at the end of October with good roots and lay them up to their leaves in a frame, or in some place where they can be protected from the frost with mats, straw, boughs, or canvas. I think Snow's is at present unsurpassed by any other variety, and is especially useful for this crop, as it is hardier than any other I have tried.

In the first week of April sow a little of about three sorts to stand in the ground all the winter. Snow's Winter White will come in for cutting in March and April, also Adam's Early and others, but they are more tender than Snow's. Plant out in June the same as with the previous crop in well prepared ground. The best thing to do with this crop is during October or November to place the spade under and turn them over into a trench previously dug, and the next row into that vacated by the first, raising the soil well up to the leaves. Be sure and not turn them over too early. I once almost lost a fine crop by a fortnight of summer-like weather which nearly killed them all, but if done at the right time they, thus protected, may pass through the winter successfully. At the end of April sow three more sorts, which will come in for cutting during April and May. I like Dilcock's Bride; I have found it decidedly the best, followed by Dalmeny Park and Salter's Imperial. Though old I do not despise them, as they are extra good for this sowing. These are hardy and require no protection.

In the middle of May sow two or three sorts. I have found Cattell's Eclipse come in well. I have had plenty of it to cut, together with Cauliflowers from the autumn sowing. There are of course numerous sorts that will no doubt come in just as well as those mentioned. The district has much to do with them, and also the time of sowing and planting. If a good system is set down by a young beginner, and carried out, he will be able to cut heads all the year round, unless the winter is very severe. The reader need not keep to the sorts named here, but attend to the time of sowing and planting to get them in at a given time. During May sow Purple Sprouting Broccoli. Be sure and have a good supply, as this is certain to withstand the frosts, and come in, perhaps, when many others may be annihilated by hard winters. No special treatment is required, only good open land sheltered from north or east, plenty of manure, and well dug ground.

SAVOYS.

Prepare a good piece of ground on a warm border for the seed bed. It can be set out to look neat, as is usual, in well kept gardens. Sow broadcast and rake the seed in. The ground can be trodden either before or after sowing, but if it is wet this should not be done. The best time to sow is at the end of March or the beginning of April. As the plants become large enough they can be placed out, and treated in all respects like the Cabbages. Some, amongst them myself, are compelled by scarceness of ground to plant them between other crops, but this should be avoided if possible. Plant out some in May, June, and July; the quantity must depend upon the spaces at disposal. It is a mistake to overdo it, as the ground is better if it can have a dressing and digging for the winter.

COLEWORTS.

These are often depended upon for winter use, others grow them for cutting during the later summer and autumn months. I do not put them in the place of better members of the same family, such as Ewing's No. 1, Sugarloaf, and others; those who do can sow seeds in April, May, and June, and treat like

Cabbages, only they require much less space. For procuring plants for winter and spring use sow in July, and plant out the main crop during August. Others can be planted at different times up to November. Coleworts are very hardy, and if the winter is not severe and the spring early they can always be turned in or cleared off, but if it is the reverse they will be found exceptionally useful.

BRUSSELS SPROUTS.

If one variety of the Cabbage family requires better ground than another it is that named above. No labour or manure can be wasted upon it, the length of the stem and the quality of the Sprouts are the first considerations. If ground is plentiful take, say, the Onion bed if not wanted for spring Cabbages, dress well with manure and turn it in, then sow with Vetches or Tares, and during the early spring apply manure, and trench the ground again, using a little lime. This can lie fallow till the planting time. If this is not possible the ground can be well trenched in the autumn, sown with early Peas, such as Sangster's No. 1 or Chelsea Gem in December, and the Brussels Sprouts planted between. The former is much the better, and can be adapted to any of the autumn or winter crops.

Numbers of good Brussels Sprouts are at present in commerce, but there is one in the trial grounds at the Royal Horticultural Society's Garden that I shall try and find space for when it is sent out by Messrs. J. Veitch & Sons. I have noticed it two years, and it far exceeds any other, but it will not want my praise when it receives the Chiswick brand. At present I have found Scrymger's Giant extra good. I should sow in the end of March or the beginning of April, as directed for other crops. Plant out on the ground as soon as the plants are fit. They must not be neglected either in the seed bed or after, but must receive every attention as to watering, hoeing, &c. Some top them after they have done growing, but this I do not advocate, and think it tends to do them more harm than good. Other plantings can be made from the same bed, or from other sowings. One good crop is all I try to obtain.

OTHER WINTER GREENS.

These are all very useful, but are too numerous to classify and are also too often a repetition of the same. Whether they are the Dwarfed Curled or the Tall Curled Greens they can be relied upon for a certainty. The Tall is very hardy, standing severe frost, and are also delicious in frosty weather. The Variegated is useful for garnishing. The Cottagers' Kale is serviceable. In my opinion mistakes are often made, of which I myself am guilty—namely, in sowing and planting too late. Sow the seed in March and April, and plant as directed for other members of this family. They do not exhaust the ground nearly so much as Cabbages.—G. A. BISHOP.

THE NATIONAL CHRYSANTHEMUM SOCIETY.

THE General Committee of the above Society met at Anderton's Hotel, Fleet Street, on Monday, December 2nd, at 7 P.M., the principal business being to fix the date of the Centenary celebration for 1890, and to appoint Judges. R. Ballantine, Esq., took the chair, and there was a large attendance of members, including the representatives of affiliated Societies. The Hon. Sec., Mr. W. Holmes, reported on various matters in connection with the November Show at Westminster, and announced that the annual dinner will be held at Anderton's Hotel on Thursday, December 19th, at 6 P.M. sharp, when Lord Brooke has promised to preside, and will be supported by Sir Edwin Saunders, Sir Lewis Pelly, and others. Arrangements have been made for a good programme of music, and it is expected that the gathering will be highly satisfactory. It was also reported with regard to the provincial Show at Hull that an excellent Exhibition was secured, comprising over 500 more cut blooms than were secured at the same Show last year, and the receipts were also largely in excess. Some members of the National Society visited York by invitation, and were well received. A vote of thanks was accorded to the officials of the York Society for their courtesy to the deputation, and a similar acknowledgment was, on the motion of the Chairman, directed to be sent to the Ghent Society for the gold medal presented to the National Society at the recent Centenary Exhibition. The silver medal, recommended by the Floral Committee for Mr. R. Owen's collection of cut blooms at the recent Westminster Show, was unanimously granted. Several Societies were affiliated, including one at Launceston, Tasmania, and forty-one members and Fellows were elected, bringing up the total to 673.

The recommendation of the Centenary Sub-Committee (previously

held under the presidency of Mr. E. C. Jukes) with regard to the date of the celebration next year was then carefully discussed. Mr. Jukes reported that it had been resolved to suggest November 11th, 12th, 13th, and 14th as the most suitable dates after a careful consideration of all matters, as it was desired to render the Show as thoroughly representative as possible, and it was feared that it would be difficult to secure specimen plants in the preceding week. An amendment was, however, moved and seconded to the effect that that the 4th, 5th, 6th, and 7th would be the best dates. A number of plant exhibitors thereupon expressed themselves decidedly against the earlier dates, and the amendment was withdrawn, the original motion being carried unanimously. It was explained that it is only intended to make the first two days a competitive display as usual, the remaining two-days Exhibition to be provided by special arrangement with exhibitors.

The next matter was the appointment of Judges, the following being recommended and unanimously elected:—For cut blooms, Messrs. George Gordon, Lewis Castle, J. Douglas, R. Dean, J. Kendall, and W. G. Head; for specimen plants, Messrs. Donald and Prickett; for fruit and vegetables, Messrs. A. F. Barron and J. Roberts. Six reserve Judges were also selected, and this concluded the business of the meeting.

CHRYSANTHEMUM LUNE FLEURI.

COMPARATIVELY few additions to the Pompons are now obtained, and this renders any novelty of merit all the more welcome. Mr. R. Owen of Maidenhead exhibited a large collection of new Chrys-

FIG. 60.—CHRYSANTHEMUM LUNE FLEURI,

anthemums at the meeting of the National Chrysanthemum Society's Floral Committee on November 12th last, amongst them being several that were found worthy of certificates, a silver medal being awarded for the whole exhibit. The Pompon Lune Fleuri (fig. 60) was included with the certificated varieties, and, though, perhaps too small to satisfy the taste of some exhibitors, it is just the style that we ought to look for in this type of Chrysanthemum. The blooms are globular, very even, somewhat in the way of Model of Perfection, but of a rich deep golden colour, very distinct, and it is likely to be useful both for general cutting purposes and for exhibition.

CHRYSANTHEMUM GROUPS.

SOME remarks respecting groups of Chrysanthemums are given on page 480, and the admirable character of those shown in competition at the recent Hull exhibition is there noted. The illustration (fig. 62, page 489) has been prepared from a photograph of the best of them—namely, that which gained the premier honours—a silver cup—for Mr. J. P. Leadbetter, gardener to Arthur Wilson, Esq., Tranby Croft, Hull. As we noted last week, the winning group was distinguished by the high quality of the bloom, the free effective style of arrangement, and the neat margin of foliage plants. The latter were of moderate size, clean healthy specimens, not so large as to crowd the Chrysanthemums or detract from their beauty in any respect. Perhaps it could have been improved if the plants had been a little less rigidly staked, but altogether there were fewer defects than such groups usually possess.

CHRYSANTHEMUMS AT CHARLTON.

HAVING paid half an hour's visit to the gardens of the Charlton Brewery at Shepton Mallet, I was greatly struck by the good Chrysanthemums to be seen there, which would have done justice to the exhibition board, but unfortunately Mr. Curry could not get permission to exhibit. Though not large in number, the blooms of the following varieties were very fine:—Lord Alcester, this has been good in this neighbourhood generally; Boule d'Or, Val d'Andorre, Fair Maid of

Guernsey, Hero of Stoke Newington, Mrs. G. Randle, Hiver Fleuri, Queen of England, M. C. Audigui, Golden Dragon, Cherub, &c.

The stove, which is small, contains some healthy plants, comprising *Dracena terminalis*, a good pot of *Microlepis hirta cristata*, *Pandanus Veitchi*, &c. In the other houses may be seen excellent *Freessias*, strong growths, promising well; *Primulas*, *Lachenalias*, and *Zonal Pelargoniums*. A few *Orchids*, including *Dendrobiums*, *Celogynes*, and *Oncidiums*, are now in flower. *Cinerarias* are promising well, and everything is creditable to Mrs. Berryman's gardener, Mr. Curry.—A. G. FRAMPTON.

A DAMP INDICATOR.

MR. F. W. BECK, a florist at East Grinstead, and Honorary Secretary of the Horticultural Society there, is the inventor of the small instrument represented in fig. 61 for registering the amount of moisture in the atmosphere of plant houses, dwellings, machine rooms, and other places where injury is done by an excess of damp when the excess is not suspected. We have been informed that a damp bed suggested the production of something that would indicate whether a "strange bed" was damp or not. The instrument has been found useful in that and many other respects, and is largely sold in this country and America. It is so sensitive that when the case is opened the indicator moves by the action of the breath, just as the mercury in a thermometer rises under the influence of heat applied in the same manner, the extent of damp being determined by the figures to which the small thread-like detector points. Particulars accompany each instrument, which is about twice the size of the illustration, and generally resembles a small aneroid barometer.

FIG. 61.—DAMP INDICATOR.

PLANTING FRUIT TREES.

APART from the question of manurial matters, and, as a preliminary step to the consideration of making plantations of fruit trees, we may offer a few remarks on the texture of soils. Drainage, it is well known, exercises the most powerful influence on the texture of water-logged soils. By removing superfluous moisture a free admission is afforded to the ameliorating effects of the atmospheric action; but even the most thorough drainage will not suffice on many soils as to fruit culture. The oozy and elastic bog wants consolidation, combined with a mechanical separation of its particles; the clay requires a gritty or sandy medium in order to permit the rains to percolate or slowly pass through it, and in consequence the air to enter freely; whilst the loose sandy soil requires some body to give adhesion to its parts, and, indeed, as the opposite of the clayey soil, to prevent the rain from passing through too rapidly, and carrying away manurial matters in its course.

Those, therefore, who are about planting a whole garden, or section of one, at once, should thoroughly consider this question, and, after examining well the soil and subsoil, endeavour to procure eligible materials for correcting faults in the staple. Where surface soils are naturally inclined to sand either marl or clay will prove suitable to mix with them; or, what is better by far than either, the furrowings from old pasture lands of a strong or stiff loamy character. The latter, however, is only within reach of a few, and marl is the next best thing, but this also is not found everywhere. Where clay is very stubborn we think that a burning process might be applied profitably. In addition to these materials any old vegetable matter, whether it be decayed weeds, leaves, old tan, or, indeed, anything that carries the appearance of humus, may be blended with advantage. If, on the contrary, the surface soil is very adhesive, pure sand, sandy soil of a loose character, and even coal ashes, may be incorporated with the volume of soil, and, indeed, a proportion of the decomposed vegetable matters suggested for the sandy soil. On such heavy soils we would, by all means, recommend spring planting; and, in that event, the holes should be excavated immediately in order to undergo a long winter's action for the sake of breaking down the adhesive material. If the whole plot is to be improved trenching and ridging should be resorted to; here, again, the winter's frost will amply compensate for the difference of a few months and save labour.

In rendering boggy soils suitable for fruit-tree culture a somewhat different course must be pursued. Here, however, it is necessary to distinguish clearly the character of the dark material. Some boggy soils are of an elastic character—that is to say, they will rebound on a stamp of the foot; this merely shows that much organised matter exists in the main composed of bygone generations of sphagnum mosses, together with weeds and grasses, in a

state of decomposition. This is above all, perhaps, the most inelible character of any for fruit-tree culture; nevertheless, it is not a hopeless case; albeit, much culture is requisite. Where a considerable depth of such material exists burning may be had recourse to. This will correct the acidity and produce ashes, which will be of much utility in opening the texture of the soil. However, before other operations take place, the most complete drainage must be had recourse to. Without this all other operating will be totally inefficient. Such soils require both sand and clay, or marl, after being rendered tolerably dry. These materials, well incorporated with the native soil, will, with culture, remove the spongy character of the mass and produce a degree of solidification which will give a permanency and stability to the crops.

We have been making these remarks with a view to assist those who are about reclaiming ungenial plots of land; for, in going through the country, how many such enclosures we see, some taken from the sides of commons, others from the roadsides, left uncultivated in days when land was of less value and when the population question did not press so heavily. Moreover, hundreds of little nooks have been split from out-of-the-way corners of farms, and not unfrequently composed of a soil of somewhat sterile character. Most of such little enclosures, as we have seen them, are placed under culture without due preparation; too little attention is paid to the amelioration of the staple, and, as a necessary consequence, fruit trees in a number of cases do not succeed and prove as remunerative as they ought, for we would not only have the cottager to secure his own dumpling Apples, but to pay a portion of his rental annually by the sale of Apples, Pears, Black Currants, &c., as the case may be.

Our hints here, then, will, we trust put people on the alert to obtain forthwith some material to improve the texture of their soils according to the principles here explained. One thing we had almost forgotten: those who are improving stubborn plots in the vicinity of towns should always keep a look out for the old mortar or plaster from the pulling down of old buildings. This is a capital ameliorator.—E.

THE WINTER MOTH.

FROM almost every part of England, and many places in Scotland, reports reached me of the serious damage done to fruit trees during last April and May by the caterpillars of the winter moth, *Cheimatobia brumata*. It is by no means particular as to its diet, and the list of trees and shrubs upon which the insect feeds is a long one, but I think it is specially partial to the Apple, Plum, and Filbert. The revolutions or changes in insect life which cause a special abundance of a species during one season may often result, as we know, in a scarcity of it during the next; still, there being a possibility that after a profusion one year the following season may show even larger numbers, there is good reason for doing what we can now to protect ourselves from serious losses through these caterpillars in the season of 1890. At this moment we are in what has been called the winter campaign, and have good opportunities of destroying the parent moths, or preventing the deposition of their eggs, also of removing eggs which have been insidiously laid.

That able entomologist Newman has justly said that this winter campaign is of the greatest importance, and accomplishes more than all the methods for killing the caterpillars or the pupæ. Indifferent to cold seemingly, the moths emerge from the pupal condition some time between the beginning of November and the end of the year. I have most frequently seen them in December, but evidently there is a succession of them, and they do not appear all at once, but gradually. The particular date [depends, no doubt, partly upon the weather in early winter; partly also I think upon the date when the caterpillars were full grown. In colouring the male moths are greyish brown, not very noticeable when sitting on fences or trunks of trees; the females are stout, also brown, but have only rudimentary wings, so they cannot fly, and creep about in spiderlike fashion. Having emerged, it is then their object to place their eggs, which number nearly 200, in little masses upon stems or branches, upon leaf or flower buds, and sometimes they attach them to the dried leaves which may chance to remain on the trees. It is easy to detect these by daylight, and remove them with the aid of a lantern. They may be sought after dark, as they appear frequently to keep near the earth till dusk, when they begin their pilgrimage to the trees. I cannot but think that some of them at least must fall victims to insect-loving birds, though I have not seen them seeking these moths. Digging over soil in which the pupæ may lie is advantageous if done in good time; it exposes them to various enemies, and to the influence of autumn rains or early frosts.

But one of the best methods going is the surrounding the stems

of trees with a sticky or clogging substance of some kind, over which the moths are unable to crawl. This has been long practised in Germany, though I will not say we borrowed the idea from that country. There the gardeners have been in the habit of putting round choice trees a sort of frame, having a projecting coping, upon which tar is daubed, and renewed as may be necessary. An objection to this is that it is rather expensive, therefore not applicable to orchards, and hence has arisen the practice of smearing the tree itself to prevent the moths ascending. Several compounds have been tried. The most suitable of these is a combination of equal parts of cart grease and Stockholm tar. Newman observes that it tightens the bark somewhat, so that this should be slit subsequently. The complaint has been made, however, that a sunshiny day, even in winter, will make the tar soak in, which produces an injurious effect, and Newman suggests a preparatory coating of whitewash, made of whitening and glue size, upon which the sticky composition is then laid. Others have tried placing in the earth round, but not touching, the trees ropes or hybands wetted with a mixture of tar and oil. Miss Ormerod speaks in favour of throwing about the stems gas lime which has been exposed for awhile to the air, and this remedy is of utility for espaliers or walls; but as yet it has not been sufficiently tried by gardeners and growers of fruit. It is one argument for postponing the operation of pruning till after Christmas, that by this means boughs and twigs which may contain eggs of this or of other species of insects are removed, and should be speedily burnt.

A very important question has arisen with reference to these precautionary measures—namely, what is the cause of their possible failure, as in several reports concerning the winter moth sent from various districts gardeners stated that the trees had been carefully coated, but nevertheless the caterpillars appeared in swarms during the spring. It is desirable to ascertain what is the explanation of this, or at least what is the likeliest of any that may suggest themselves. As I have stated, it is the habit of the caterpillars when full grown to descend to the ground, in which they bury themselves for the approaching transformation. I have never noticed an exception to this, nor have my entomological friends; but supposing it to be the fact that the caterpillars sometimes remained in their webs to become pupæ, the moths would be quite secure from entanglement or stoppage upon the stems. It is barely possible that when feeding on lofty trees they might not all descend, but I do not think this gives the clue. Still, next season it will be desirable to examine carefully into this point, as we do often meet with singular aberrations of habit. Certainly all webs seen upon trees, whether at the time they are feeding or later, should be carefully removed. Something depends upon the date when the composition was laid on the trees. Supposing the moths had emerged earlier than usual, evidently it would be of no good taking this step in December when the eggs must have been deposited. Yet the weather last autumn was not such as to hasten their appearance, and it might be just the opposite error, the composition being used too soon, perhaps some weeks before the insects emerged; if so, it would become partially dried, and they would be able to cross. This might be accomplished also by young caterpillars, for it must be remembered that though some moths get into the tarry substance and perish, others remain beneath it unhurt, and probably lay their patches of eggs. In the spring the caterpillars emerging from these may travel up the trees. The conclusion of the matter is that whatever is placed round the trees should be examined daily for results, and any patches of eggs that may be detected should be crushed.—ENTOMOLOGIST.

JUDGING from the letter of Miss Ormerod's in this Journal (p. 459) that no practical remedy has yet been discovered for the caterpillar pest on fruit trees after they once get possession, I hope you will pardon me for saying how I cured an Apple tree last year when a crop of fruit appeared hopeless. I simply made a fire under the tree with a lot of rubbish, making a dense smoke, and kept it going for a few days with any weeds that came to hand. The result was that I had a capital crop of very fine fruits, the best the tree had ever borne. Usually the fruit was much speckled right to the core, but last year I did not see any. If you think this will be of any service to your readers make what use you like of it.—C. G.

PLANTING YOUNG VINES.

IF I recommend one system of planting young Vines more than another it is planting them in a growing condition with their roots intact. I disapprove of the principle of washing the roots of young Vines previous to planting. I think I also said that for years I had failed to see the wisdom of following the orthodox principle of shaking away all the soil in order to spread out the roots. It is to my mind a barbarous system of root-pruning, and I fail to see how

Vines can be expected to make such luxuriant growth the season following as they would if planted without being disturbed at their roots to such a serious extent. I am aware that Vines with careful treatment will do well even on this principle, as well as many others, and I tried to show on page 230 of this Journal for March 21st that good Vines could be established by a variety of systems.

The size of the canes given by your correspondent, "J. L. H.," is not extraordinary. I have seen Vines grown in one season exceed 2 inches in circumference. I have some Vines considerably stronger, two years old, planted last autumn while the foliage was fresh, that have carried a crop of Grapes. It is very difficult to draw comparisons, and the only means of doing so, and arriving at the system most preferred, is to plant on the two systems, side by side, and note the results. I am acquainted with a grower of Grapes for the market who planted his first house according to the established principles and by the advice of one skilled in the culture of Grapes, but when planting his next house he departed from orthodox views, because the preparation of the border was too costly an operation, and followed a common-sense view that did not entail half the labour or expense, and the results have been the more satisfactory of the two. What is needed in the establishment of Vines is sound judgment, guided by the circumstances of each case, which, I am convinced, will often lead to better results than strictly following some rule of thumb.

I am no advocate for that extra luxuriant growth that is often seen in young Vines. It is full of pith frequently, and cannot be thoroughly matured. I prefer to this forced growth, that must tell against the constitution of the Vine in after years, firm wood of moderate strength that can be thoroughly matured. Vines of this nature build up from the first good constitutions and are capable of bearing fruit and improving in strength and vigour, while overgrown ones often fail, or partially, when they have to undergo the strain of fruit bearing.

I am glad your correspondent has built up his Vines on sound principles, preferring firm sturdy growth to mere size, which is very frequently deceptive.—W. B.

CANTERBURY BELLS.

THIS is one of the most useful hardy biennials we have either for conservatory or church decoration. It is easily cultivated in pots, and when in bloom is highly effective. The plants naturally assume a pyramidal form, and grow to the height of from 2 to 3 feet, and they flower freely from top to bottom. The colours of the flowers consist principally of shades of blue and pure white. To grow it well the seed may be sown on a sheltered border some time in May, and the plants, when sufficiently large, lifted and placed into 60-sized pots, in a compost of loam, leaf mould, and sand, transferred to a cold frame and shaded for a few days until the roots have taken hold of the soil. The shading must then be removed and air admitted freely on all favourable occasions. When the plants have filled the pots with roots shift them into their largest pots; we find 6 and 7 inch the most useful for all purposes. The soil used consists of more loam and less sand and leaf mould than was used at the first potting, and the compost is not enriched with manure of any kind. The plants may now be placed in the open on the side of a gravel walk, or on ashes in the frame ground, where they can be properly attended to and regularly supplied with water, as no plant suffers sooner from neglect than this.

About the end of September or the beginning of October the plants are thoroughly cleared of all dead and decayed leaves, and placed in a cold frame for the winter. Although the Canterbury Bell is perfectly hardy and will stand a considerable amount of frost with impunity, it will not endure damp and rain when grown in pots. The plants must have plenty of air during winter, and in good weather we remove the lights to dry the foliage and prevent it damping.

In the month of April the plants are taken out of the frame to make room for bedding plants, and plunged in any convenient piece of ground until they come into flower, when they may be removed to the conservatory as required. As soon as they show their flowering spike they are staked (one stake in the centre of the pot is sufficient), tied, and watered after this with weak liquid manure two or three times a week. If the plants are properly attended to, and all blooms picked off as soon as they begin to decay, they will last a long time in flower, and give general satisfaction. They cost little in growing, and answer the purpose of decorating church or mansion as well as the most expensive. In my opinion the Canterbury Bell deserves to be more extensively cultivated in pots for decorative purposes that it is at present, and

I have no doubt when its good qualities are better known it will become a general favourite.—HUGH PETTIGREW, *Cardiff*.

EVENTS OF THE WEEK.—The Royal Horticultural Society's Fruit and Floral Committees will meet at 11 A.M. on Tuesday next, December 10th, at the Drill Hall, James Street, Westminster. The Orchid Nomenclature Committee will also meet at 11.30 A.M. in the Lindley Library at the offices, 111, Victoria Street, on the same day. The National Chrysanthemum Society's Floral Committee will meet at the Royal Aquarium, Westminster, at 2 P.M. on Wednesday, December 11th, the usual business to be followed by a complimentary dinner as terminating the year's work.

— **ROYAL HORTICULTURAL SOCIETY.**—At the last meeting of the Council of the Society Mr. A. H. Kent, A.L.S., of the Royal Exotic Nursery, Chelsea, was unanimously elected an honorary Fellow under byelaw 15.

— **THE WEATHER IN THE SOUTH** has become very winterly, sharp frosts prevailing, and exceptionally low temperatures have been registered in some districts. On several mornings the thermometer has stood at 18° Fahrenheit. A little snow has fallen, but the weather generally has been dry and clear.

— **THE WEATHER IN THE NORTH.**—Last week winter seemed upon us with a bound. On the night of the 25th ult. frost set in, with snow in many parts of the country. In South Perthshire but little snow fell; 5°, 9°, 7° of frost were registered on successive nights. Thaw began on the evening of the 28th, and since then we have a return of dull, drizzly weather. Many varieties of flowers can still be had, and a Rose bud worth gathering peeps out here and there.—B. D.

— **DULWICH PARK.**—We understand the tender of Messrs. Cutbush for planting Dulwich Park, an area of seventy acres, at the cost of £1014, was accepted as urgent in order that the trees might be planted before Christmas.

— **SHOWS FOR 1890.**—We are informed that the Portsmouth Chrysanthemum Society will hold their Show next year on November 5th, 6th, and 7th. The Kingston-on-Thames Society's Show is fixed for November 11th and 12th. Mr. J. Wright is engaged for both those shows. The National Society's Centenary Celebration will take place on November 11th, 12th, 13th, and 14th, the two first days only being for a competitive display as usual.

— **MESSRS. J. CARTER & Co.,** High Holborn, send us a sample bulb and illustration of *NARCISSUS TAZETTA* GRAND EMPEROR, named "The Good Luck Lily," "Chinese Sacred Lilies," "Joss Flowers," and "Water Fairy Flowers." It appears to be a strong-growing and very free-flowering variety of the *Polyanthus Narcissus* group, and it is shown in the illustration growing in a bowl of water. The importation is said to be "direct from the mountainous districts of northern China."

— **IN** the conservatory at Firbeck Hall, Rotherham, there is a fine plant of *LUCULIA GRATISSIMA* in flower, just now forming a screen 15 feet wide by 8 feet deep. It has about 500 blooms on it, of such a size as are seldom seen, and of a pleasing pink colour at this dull season. The conservatory is large, but the whole house is filled with the delightful fragrance. Mr. Egglestone, the gardener, planted it out in the bed of the conservatory a few years ago, and he may well be proud of such a grand result.—VISITOR.

— **IN** our issue of November 23th, the report of the EDINBURGH SHOW (the cup class) the third prize winner reads—G. Cockburn, gardener to G. Burden, Esq., Lingdale Lodge, Birkenhead. It should be G. Burden, gardener to G. Cockburn, Esq., Lingdale Lodge, Birkenhead. At the Show in question it is said the names of all the winners were not attached to the stands, and as they had to be searched for in a catalogue, it would not be surprising if several errors occurred.

— **THROUGHOUT** Scotland, as well as in the south, **TUBEROUS BEGONIAS** are now favourite flower-garden plants. They bear much wind and wet without injury, and the flowers are attractive in form and colours. Two or three years ago they could not be bought under 6s. a dozen, now I have plenty of the same kind offered at 20s. a hundred, and this will tend to make them more popular. As grown in pots those under the care of Mr. David Thomson, Drumlanrig, surpass any I have seen. Many of them are bushes about a yard through, and the blooms were 8 inches in diameter.—M.

— **GARDENERS' ORPHAN FUND.**—At Worksop, Notts, on November 20th, a grand and highly successful concert in aid of the above was held under distinguished patronage, promoted by the gardeners of the district—viz., Messrs. Egglestone (Firbeck), Horton (Welbeck), Jefferson (Carlton House), Mallender (Hodsock Priory), Sutton (The Manor), Woods (Osberton), Henderson (Thoresby), Treasurer, with Mr. Gleeson (Clumber), Hon. Sec. F. J. S. Foljambe, Esq., made a short speech to open the concert, setting forth the claims of the Society on the public at large. After the first part of the programme had been gone through, Mr. Mallender, on behalf of the Committee, thanked the performers for their services, and the audience for coming in such numbers. The total receipts were £80 5s., leaving the handsome sum of £57 10s. to go to the general fund. Altogether the concert was a wonderful success, and reflected most creditably upon the energy and tact which was displayed by the Committee, and most especially the courteous Hon. Sec., Mr. Gleeson. At a meeting of the Executive Committee of the Fund, held on Friday last, among other contributions announced was a sum of £12, the result of a concert at Chiswick, and as Mr. J. Barry had obtained upwards of £5 of that sum by the sale of tickets, he was placed on the list of life voters in accordance with the rules.

— **WE** regret to announce the death of **MR. GEORGE MARR**, head gardener to H. Silvertop, Esq., Ministracres Hall, which took place on December 1st. Mr. Marr was forty-five years in the above family, and for the last thirty-five resided at Ministracres. He was in his seventy-eighth year, and was one of the oldest and most respected gardeners on Tyneside. He was well known at all the local shows, both as an exhibitor and judge, and one of the old school of gardeners, fast dying out. He was born in Fifeshire, served his time in the Earl of Minto's gardens at Balcarres, and went from there to the Botanic Gardens, Edinburgh, to study botany under the late Mr. McNab. Thence he removed to the service of the family with whom he died. To his last he could tell the name of every wild flower that was brought to him.

— **DEATH OF MR. HENRY CURTIS.**—Mr. Henry Curtis, head of the firm of Curtis, Sanford & Company, Devon Rosery, Torquay, died rather suddenly at an early hour on the morning of November 26th from heart disease, at his residence at St. Helier's, Torre Hill. The deceased gentleman was in his seventieth year. He came of a family of botanists, being the grandson of William Curtis, author and originator of the "Botanical Magazine" and "Flora Londinensis." The late Mr. Curtis was himself author of "Beauties of the Rose," and was a very enthusiastic and successful Rose grower. He was also a medical electrician of much skill. Kindly and gentle, Mr. Curtis was held in the highest esteem. He will be much missed in Torquay and the neighbourhood.

— **TOMATO CULTURE IN THE OPEN AIR.**—In Colonel Turberville's garden at Ewenny Priory Mr. George Hawkins grows Tomatoes in the open air with noteworthy success. They are planted at the bottom of a low brick wall under a span-roofed glass house, and trained up about 3 feet. They are mainly confined to single stems, kept very free of foliage. Some of the fruits had formed so near the ground as to touch it. They were a crowd of clusters on every part. Individually many of them would weigh 8 ozs. They were ripening fast early last September. The crop was a picture, and I regarded it as the best in the open air I had ever seen.—J. M.

— **EAST ANGLIAN HORTICULTURAL CLUB.**—A meeting having for its object the formation of a Horticultural Club for East Anglia was held at the City Arms, Norwich, on Thursday, the 21st ult. Taking advantage of the occasion of the Norwich Chrysanthemum Show, which was held the same day, when a large number of gardeners annually visit the city, a circular was issued convening the meeting on that date. A large and influential gathering was the result, many of the best-known gardeners in the county being present. Mr. G. Daniels, Norwich, presided, and among others present were Messrs. Allan, Gunton Park; Baker, Marlingford Hall; Bartlett, Earlham Hall; Bole, Somerleyton Hall; Gilbert, Sennowe Hall; MacMillan, Oakley Park; Cork, Norwich; Morris, Milton House; Woodhouse, The Plantation, &c., &c.

After a friendly discussion it was unanimously agreed that a Club having for its aim the advancement of the science of horticulture in the eastern counties be formed, and with that view a Committee was elected to organise future procedure, Mr. Morris of Witton being appointed President for the ensuing year. Members were enrolled freely, great hopes being expressed of the outcome of the meeting.

— FROM Ashton Court Gardens we have received some of the earliest and best forced LILIES OF THE VALLEY we have ever seen. They are from home-grown crowns, and we hope shortly to give some notes on their culture.

— ONION, BLACK DOUGLAS.—I should like to know the parentage of this new Onion. As grown and shown by Mr. Murray it appears only as a magnified form of the old Blood Red, and until I know better I shall regard it as such.—K. G.

— CARNATION W. M. WELSH.—This is a recently introduced border Carnation of more than ordinary merit. It is a robust grower, most profuse in flowering, and as a late variety in the open air it attracted my attention above all. The flowers are of average size, the colour a clear crimson scarlet, and its general good character, including its extra late habit, will recommend it to many.

— CELOSIAS are not grown so much as they ought to be for the embellishment of the conservatory and greenhouse in summer and autumn. I have this season seen them arranged with telling effect in groups of plants at shows, and their graceful heads adapt them admirably for this use. But the half Coekscomb half Celosia-like heads obtained from many packets of seed are not encouraging, and if anyone would introduce and perpetuate a strain with perfect feathery plumes they would benefit themselves and growers generally.

— POTATO VICTORIOUS.—I am glad this new Potato gained a certificate of merit at the recent Vegetable Conference. Half a dozen years ago ten new seedling Potatoes were sent to me for trial. None was specially recommended, all were to go on their own merits. Being partial to a good mealy tuber, I began weeding out from my first crop. Until this year the variety which has since taken the name of Victorious was my only selection from the original ten, and I take as no small compliment to myself that I managed to hit on the right sort as well as Mr. Laxton. I had no communication with him on the subject all through, but the results were parallel.

— AMERICAN BLACKBERRIES have never won my approval. I have been unable to grow or find any of them to merit ordinary praise. I have this year travelled almost from Land's End to John o' Groat's, and have not once met with a good crop. I have inquired in likely quarters, but with no result. How is it? Are they not grown; or have they failed? Wild Blackberries have been unusually plentiful this year. A good season for them should also be good for the Americans, and yet I have been unable to find them. I feel sure if our natives had received the same culture as has been given to some of those in question they would have produced astonishing crops, and I am inclined to advise those who have no wild Blackberries growing in their neighbourhood, but who like the fruit, to try a few scores of plants from a friend's hedgerow.—SOUTH WALES.

— ARTOCARPUS CANNONI.—Specimens of this really handsome ornamental stove shrub are now in full beauty of foliage at the Birmingham Botanical Gardens, and it is a lovely plant for decorative work. It was received from Mr. William Bull under the name of Ficus Cannoni. The plant is thus described in Nicholson's "Dictionary of Gardening":—"Leaves alternate, petiolate; petiole and midrib bright red; upper surface glossy, of a rich full bronzy crimson hue, beautifully tinted with purple; under surface bright vinous red. The leaves vary much in form; some are simple and cordate at the base, with the apex irregularly lobate; some have the apex regularly three lobed, with short entire lobes; others, again, are deeply three lobed, being divided nearly to the base, the segments, of which the centre one is the largest, being slightly sinuate lobed. This is a most distinct and handsome ornamental-leaved plant." Mr. Latham finds the plant of easy cultivation, moisture and warmth being two essential points, and a soil of fibrous loam and peat and good drainage.

— Mr. J. MALLENDER sends the following SUMMARY OF METEOROLOGICAL OBSERVATIONS AT HODSOCK PRIORY, WORKSOP, NOTTS, FOR NOVEMBER:—Mean temperature of month, 43.2°. Maximum on the 7th, 63.0°. Minimum on the 28th, 28.1°. Maximum in the sun on the 7th, 106.0°. Minimum on the grass on the 27th, 20.0°. Mean tempera-

ture of the air at 9 A.M., 42.8°. Mean temperature of soil 1 foot deep, 44.8°. Number of nights below 32°, in shade seven, on grass twelve. Total duration of sunshine, forty-four hours, or 17 per cent. of possible duration. We had thirteen sunless days. Total rainfall, 0.42. Rain fell on thirteen days. Wind, average velocity, 8.0 miles per hour; velocity exceeded 400 miles on two days, and fell short of 100 miles on eight days. Approximate averages for November:—Mean temperature, 41.7°; rainfall, 2.04 inches; sunshine, fifty-one hours. Remarks:—A mild, calm, and very dry month; rainfall less than half that recorded in November in any of the previous fourteen years.

— ROYAL METEOROLOGICAL SOCIETY.—The first meeting of this Society for the present session was held recently at the Institution of Civil Engineers, Dr. W. Marcet, F.R.S., President, in the chair. Nine new Fellows were elected. The following papers were read:—(1.) "Second Report of the Thunderstorm Committee." This is a discussion by Mr. Marriott on the distribution of days of thunderstorms over England and Wales during the seventeen years, 1871-1887. Notices of sheet lightning are included in the term, "thunderstorms." The years of greatest frequency were 1880, 1882, 1884, and 1872, and the years of least frequency 1887, 1874, 1879, and 1871. Years of greater or less frequency alternate regularly throughout nearly the whole of the period. The average yearly number of thunderstorms is about thirty-nine. The districts with the greatest yearly frequency are the south of England and extreme northern counties, and those with the least yearly frequency are Cheshire, Lancashire, and Yorkshire. The greatest number of thunderstorms occur in July, and the least in February and December. (2.) "On the Change of Temperature which accompanies Thunderstorms in Southern England," by Mr. G. M. Whipple, B.Sc., F.R.Met.Soc. (3.) "Note on the Appearance of St. Elmo's Fire at Walton-on-the-Naze, September 3rd, 1889," by Mr. W. H. Dines, B.A., F.R.Met.Soc. (4.) "Notes on Cirrus Formation," by Mr. H. Helm Clayton. The author, who has made a special study of cloud forms and their changes, gives a number of notes and drawings on the formation of cirrus under various conditions—*e.g.*, in a previously cloudless sky, cirrus bands with cross fibres, cirrus from cirro-cumulus clouds, cirrus drawn out from cumulus clouds, "mares-tail" cirrus, &c. Curved cirrus clouds, when accompanied by decreasing barometric pressure, frequently indicate that a storm of increasing energy is approaching. (5.) "A Comparison between the Jordan and the Campbell-Stokes Sunshine Recorder," by Mr. F. C. Bayard, F.R.Met.Soc. As a result of a year's comparison between these two instruments, the author found that the Jordan Photographic Recorder registered nearly 30 per cent. more sunshine than the Campbell burning recorder. (6.) "Sunshine," by Mr. A. B. MacDowall. This is a discussion of the hours of sunshine recorded at the stations of the Royal Meteorological Society. (7.) "On Climatological Observations at Ballyboley, Co. Antrim," by Prof. S. A. Hill, B.Sc., F.R.Met.Soc. This is the result of observations made during the five years 1884-1888.

THE GOLD MEDAL FRUIT ESSAY.

THIS essay is now published. It consists of 120 pages, clearly printed on good paper, and contains thirty-eight illustrations. Nothing is said here relative to the merits of the work: criticism can be more appropriately left to others. We simply print the introduction and concluding paragraph. For price, see advertisement.

"At no former period was such a widespread desire manifested as exists now for improving the condition of the industrial population, and for developing the resources of the soil in the production of an adequate supply of home-grown fruit. The necessity for the accomplishment of these objects is apparent, for on the one hand we have men in abundance who, with the aid of sound guidance, could engage usefully in the work, and on the other the extraordinary fact of not cities and towns only, but even country villages, with fruit-growing land all around them, largely supplied with Apples grown on the western shores of the Atlantic. It is true we have orchards, but of what kind? In the majority of instances they are composed of trees planted generations, not to say centuries, ago, which can only bear fruit so small, juiceless, and uninviting that consumers naturally purchase the larger and better-looking imported samples, which are so plentiful and so moderate in price. If home cultivators have not had a larger share of profit in producing the fruit supply in the markets, where rests the fault? A number of answers in the form of allegations are ready to hand, and have been so often repeated as to have become common property. Here they are:—Obstructive land laws, ecclesiastical charges, oppressive railway rates, high market tolls, salesmen's exactions, shop-keepers' extortions, free trade, and bad climate. Repeatedly have these reasons been given in all sincerity as the causes of the great importations of hardy fruit. We can admit the full force of all these impediments, but it will not be difficult to show that something remains more accountable

than them all for the above-mentioned anomaly. What is the great omission? Mark well the answer. There is not one obstacle but three—namely, a lack of knowledge on the subject of fruit, of enterprise in producing it in its best form, and of art in placing it before the public in the most attractive manner for arresting attention and commanding purchasers. Granting to Transatlantic cultivators all their natural advantages, which are possibly over-estimated, still let us not forget our own apathy, our loose methods, and our unsystematic, unbusinesslike procedure—not forget but abandon them. Proceed on sounder principles and more intelligent lines, and the time will come when we shall, to a far greater extent than now, and far more creditably, share in providing our population with the most wholesome of food, which will be increasingly required—fruit—the outcome of home effort and well-applied labour in British gardens and orchards. Let trees and bushes be planted of varieties of proved merit in soils and situations in which they will thrive, and they will be growing into fruitfulness contemporaneously with the removal of legal and commercial impediments. Thus those who take action the soonest will be the first to profit by whatever changes may be made. Even under existing conditions fruit culture, well conducted, has been of real service to many, and while land under ordinary cropping has depreciated in value during late years, that on which young orchards and thrifty trees are established has increased in price. What better testimony can be needed of the improving character of fruit culture? And what more conclusive evidence is required for its extension than the predominance of cankered trees and worn-out orchards nearly all over the country, with fruitless homesteads and treeless gardens on every hand? Let us see what can be done for those who are willing to help themselves in increasing the supply of useful, wholesome, hardy fruit.”

* * * * *

“Endeavour has been made to treat the important subject of this essay as fully as possible within the stipulations—to condense the essentials of fruit culture and fruit management into its pages; to teach soundly, and, above all, plainly, in the hope of teaching usefully those who have or can acquire land for producing fruit for their families, and for the inhabitants of adjacent towns, to the mutual advantage of all. Given knowledge on the subject, and industry, many an example proves, and some have been adduced, that—to quote the words of Alderman Sir James Whitehead, Bart., Lord Mayor of London (1889)—“There is no reason why much land should not be made three times, five times as profitable as it is now by fruit cultivation, and if the work is carried out with energy and zeal it will be of great benefit to the country we love so well.”

THE QUALITIES OF CHRYSANTHEMUMS.

[A paper read by Mr. George Gordon at Hull, Nov. 21st.]

CONTRARY to the expectations of some of my friends, it is not my intention to tax your patience with a long technical description of the properties of the several sections into which the Chrysanthemums have by common consent, been divided. Such description might be instructive, but it would be decidedly wearisome, and probably fail to promote that free discussion so essential to the success of these gatherings. What I purpose doing is to briefly touch upon a few points that appear to be of special importance, and therefore deserving of the careful consideration of those who are anxious to maintain a high standard and develop to the fullest possible extent the educational side of the exhibitions.

In the first place I have to submit that the marvellous increase in the number of Chrysanthemum societies during the past decade has not been an unmixed good. Their multiplication has created a greater degree of interest in the Chrysanthemum, and in providing additional facilities for growers to meet in friendly rivalry the newly established societies have materially assisted in extending the cultivation of the flower; but societies should do something beyond creating interest and increasing the number of growers. They should have for their chief aim improvement in culture. This they should carry out by endeavouring to set before the visitors to their exhibitions specimens of both plants and flowers in the highest possible state of perfection. Taking a broad view of what has been accomplished by societies generally, it must be stated that an immense improvement has been effected of late years. But if we examine the work of individual association we shall find that in many instances they have failed to exercise a really beneficial influence upon Chrysanthemum culture, because of the low standard of quality they have adopted. Were it necessary for the purpose of my argument I could give the names of not a few societies whose exhibitions have undergone but little improvement since their foundation. They may, perhaps, have increased in extent, but have failed to show any signs of improvement in the quality of the productions. But there is no occasion to mention their names, and it is far more agreeable to refer to societies that by setting up a high standard at the first have had an immense influence in diffusing a knowledge of the principles that must be observed by cultivators desirous of obtaining a place in the front rank. Leaving out of consideration the National Chrysanthemum

Society, which at no period in its history has failed to pay due regard to high quality, I will mention two Societies that have specially distinguished themselves in the work of improvement. These shall be the two Kingston Societies, the one on the Thames and the other on the Humber. Many of those present are acquainted with what has been done by the Kingston-on-Thames Society, and a much larger number are familiar with the work that has been accomplished by the Hull Society since its formation. It has been my privilege to take part in every exhibition of Chrysanthemums that has been held in this town, and in comparing one or two of the earlier shows with the magnificent Exhibition now being held it is impossible to avoid being struck by the marvellous change that has been brought about—a change not so much in the quantity as in the quality of the whole of the sections represented. If you ask me why these two Societies, with others that could be mentioned, have effected such an immense improvement in the quality of their exhibitions, and have exercised so beneficial an influence outside their own districts, I shall not have much difficulty in giving now a decisive answer. These Societies, recognising their duties, have adopted a proper standard, and appointed men to award the prizes who they know would carry out their wishes. This is a point upon which I do not propose to speak at any length. It is obvious that the chief object of an exhibitor in staging his plants or flowers is to obtain the highest place possible upon the prize list. In endeavouring to attain this object he necessarily presents his specimens as nearly as he can in a condition most likely to satisfy those entrusted with awarding the prizes. If the judges hold correct views on the points of perfection in the several types the exhibitor will not lose sight of the importance of finish; but when, on the other hand, the merits of the specimens are estimated by measurement, we have as a consequence at subsequent exhibitions huge plants furnished with indifferent flowers, and in the cut flower classes blooms distinguished by their large size and coarseness.

Speaking generally, too much importance is at the present time attached to mere size, and especially is this the case in estimating the relative merits of stands of cut blooms. Regularity of outline, brightness of colour, and solidity, count for little with many growers and some judges as compared with diameter. Consequently not only are the large varieties allowed to completely overshadow the smaller but not less beautiful kinds, but when the same variety comes into competition a comparatively large coarse bloom is placed before one a size smaller, but well finished. Compilers of schedules as well as judges have something to answer for in bringing about the unsatisfactory state of things that prevail in some centres. In their anxiety to assist exhibitors with a view to having their stages well filled, they allow duplicates to be so largely shown that in the case of the incurved section many of the most beautiful varieties are being slowly, but surely, pushed out of cultivation. It is not rare to meet with classes for twelve in which not more than nine varieties are required, and it is quite common to ask for only eighteen varieties in classes for twenty-four. The result in one case is to have about three types represented, and in the other not more than six or seven. I have nothing to say against the Queen of England and its numerous sports, but when they form one-half of the collections of twenty-four they necessarily overpower the smaller varieties. Moreover the exhibition, so far as the incurved section is concerned, loses much of its interest and attractiveness. If I am told there is a difficulty in filling a stand of twenty-four with distinct varieties, I must reply that the difficulty is not so great that it cannot be readily overcome. In confirmation of this assertion I would direct attention to the fact that comparatively small societies, such as those at Walton and Staines, insist upon the twenty-fours being distinct, and have seven or eight entries all more or less good. If the exhibitions are to be made useful to cultivators and attractive to the general visitors we must make them as varied as possible, by encouraging exhibitors to stage all the good varieties, whether large or small. Although the great preference that has of late been shown to mere size has most injuriously affected the incurved, what has been said with reference regarding high quality as of primary importance applies equally to all the sections. It is just as easy to shut out of the exhibitions the smaller Japanese or Anemones and encourage coarseness as in the case of the incurved.

There is yet another matter that has a general application, and that is freshness. In the case of all the sections freshness is essential, and the want of this important quality frequently places boards of blooms at a great disadvantage in a close competition. Without freshness it is impossible to have the colour at its best, and although many cultivators and some judges fail to recognise the fact, to stage each bloom in its true colour is of the highest importance. It should be remembered that it is no part of the duty of judges to take into consideration what the

blooms were a week or ten days before the date of the exhibition, or what they would have been some time afterwards had they been allowed to remain until they had attained their full development. The duty of the judges, as I understand it, is to make their decision according to the condition of the blooms when presented to them, and exhibitors who have their blooms at their proper age on the day of the show will stand the best chance of winning.

Passing on to a reference to the several sections, the incurved as representing the most perfect type may well have precedence. If we accept as one of the first principles the assertion that the incurved flower should be perfectly globular, we have in the Empress of India and its several sports a model for form, but a model varying so much that it affords scope for variation in taste and much greater scope for variation of skill in producing it. We are told that a globe is unelegant and meaningless by those unable to appreciate the graceful curves of a perfectly finished bloom of the variety mentioned as a model or one of its progeny. But I will not pause to discuss this point, but at once state

the exhibitor. Blooms belonging to the incurved group so well represented by Madame C. Audiguier and Comte de Germiny should have their florets more or less incurved, not regularly, as in the case of such varieties as the Queen of England, but sufficient to show their true character. Comte de Germiny is generally presented in its true character; but of the many hundreds of blooms of Madame C. Audiguier that I have had to examine during the season, not more than half a dozen have been in fairly good condition. They were very poor last year, and although the seasons may not have been particularly favourable, we must look to the cultivator for an explanation of the thin, flabby appearance presented by the majority of blooms, both this year and last. In the reflexed Japanese class, of which Elaine is still the best type, a certain regularity of form is of necessity admissible, and the florets should be somewhat regularly arranged and more or less reflex, although not with the formality characteristic of such varieties as Dr. Sharpe and King of the Crimson. To the multitude of varieties that belong to the third section, it is not possible to do more than refer in general terms. I

FIG. 62.—A PRIZE GROUP. (See page 483).

that the more closely your bloom approaches a spherical form, the greater will be the chance of success. The flowers should be well filled up in the centre, and the florets incurved regular, and be well rounded at the points, as indentations are disfigurements. Solidity is of hardly less importance than regularity of outline, for thinness is at once detected by the trained eye, and will heavily discount the chances of the blooms taking a high position. A common defect in the incurved is flatness, which means a low crown, a poor centre, a sharp shoulder, and a want of substance in the florets, and this default can only be avoided by good culture, as the art of the dresser will not do much to remove it.

The Japanese varieties, which rank next in importance, present a great diversity of form, but for our purposes they can be divided into three well-marked groups. These groups are the incurved Japs, the reflexed Japs, and those with florets more or less twisted. In the first and third of these groups large size is undoubtedly of importance, provided it does not, as in such varieties as Condor, Etoile de Lyon, and Mrs. F. Thompson, pass into coarseness. Size is of less importance in the reflexed Japs but it must not be overlooked. In all the sections fulness and decisiveness of colour are essential, for blooms that are thin or ineffective in colour cannot possibly render service of much value to

have already stated that the blooms should be full and bright in colour, and it will now suffice to say that each variety should be presented in its true character, as represented by the finest types at the exhibitions. I would strongly recommend prominence being given to such distinct varieties as Belle Paulc, Madame C. Audiguier, Boule d'Or, Edwin Molyneux, Stanstead White, and Grandiflorum. They usually carry more weight than flowers of more regular shapes, and I hope the quaint and fantastically formed flowers will ever continue to have proper value attached to them by judges, so greatly do they contribute to the interest of the exhibitions.

To speak of the reflexed varieties at any length is unnecessary. They are as a class very unsatisfactory, for although a hundred years have now elapsed since the introduction to Europe of the reflexed there are not half a dozen varieties that are even fairly good. Christine and its sports are very coarse, Elsie and Cullingfordi are erratic, and it is not difficult to produce blooms of Chevalier Damage that will throw inexperienced judges off their guard and ensure disqualification for the collection, as happened at one of the metropolitan exhibitions this season. The proper form of the reflexed bloom is a half globe, and it should be free from any trace of thinness or confusion in the centre.

The florets should be flat, free from notches at the top, and regularly recurve. The larger the blooms the better, provided they are free from coarseness. In many instances size is regarded as all important by both exhibitors and judges, and preference given to flowers that represent a liberal use of stimulants rather than culture of the highest class.

We have now three distinct types of Chrysanthemums with Anemone centres, and these, as you are all aware, are known as large Anemones, Japanese Anemones, and Pompon Anemones. These all agree in having an Anemone or cushion-like centre, surrounded by a fringe of ray florets arranged regularly or otherwise according to the section. In the large and the Pompon Anemones the ray florets should be flat, arranged more or less horizontally, and be circular in outline, and the disc or cushion be high in the centre and regular in outline, forming as near as may be a half globe. In the Japanese a high full centre is essential; the ray florets may be long and drooping, much curled, or otherwise irregularly arranged, but the fringe should be full. I would direct special attention to the importance of having the centres of the Anemones well developed, for although some judges prefer huge flowers with perhaps a ghost of a centre because they show "growth," whatever that may mean, flowers perfect in all their parts will in the majority of cases win. But I would not unduly exalt the centres, the rays also must be more or less perfect, and I would caution exhibitors against the practice which very generally obtains of staging old flowers having good centres from which the discoloured ray florets have been stripped, for when so mutilated they cannot possibly obtain many points.

One other section remains to be noticed, and that is the Pompons, which, if not particularly popular at the present time, are so useful as to well merit attention. I would, in referring to them, protest against the encouragement that is given to blooms of excessive size. This is done in some cases by allowing thinning, and in others by stipulating that the blooms shall be shown singly. I would submit that it is a waste of money to offer prizes that have the effect of encouraging cultivators to attempt to produce blooms of Black Douglas that will resemble undersized flowers of Julia Lagravère, or flowers of President that bear a resemblance to those of Progne when indifferently developed. Pompons should in all cases be presented in as natural a condition as possible, for when unthinned and staged in bunches as cut from the plant, they not only give visitors a better idea of their elegance and beauty, but are decidedly more attractive. I know but few hold the same opinion as myself, but I hope that as more correct views obtain, we shall have a reform change effected in the manner in which the Pompons are now presented at the public exhibitions. But so long as the schedules are prepared and the prizes awarded on the present lines, exhibitors have no alternative but to continue to grow the Pompons in a manner opposed to the development of their true characteristics.

THE CHISWICK GARDENERS' MUTUAL IMPROVEMENT ASSOCIATION.

MRS. S. A. LEE, Chiswick, has, with the object of encouraging original research and observation, again very kindly offered a sum of £10 10s. to be distributed in prizes for essays on horticultural subjects, as defined below. The competition in Classes 1 and 2 is open to all the ordinary members of the Association who have paid their subscriptions for the current year before January 30th, and attended ten meetings of the current session before February 28th. A first prize of £2, a second prize of 30s., and a third prize of £1 will be awarded in Classes 1 and 2, and prizes of books to the value of £2 will be awarded in Class 3, provided the essays are, in the opinion of the adjudicators, worthy of the prizes. All members may send in essays in one or both of Classes 1 and 2, but no member shall take more than one prize, excepting members under twenty-one, who may take one prize in Classes 1 and 2, in addition to any prize in Class 3. The competition in Class 3 is limited to the members of the Association under the age of twenty-one who have paid their subscriptions before January 30th, and attended ten meetings of the current session before February 28th.

All essays bearing a motto or *nom de plume* must be delivered to Mr. J. Barry, R.H.S. Gardens, Chiswick, not later than February 28th, 1890, each essay to be accompanied by the name and address of the competitor in a sealed envelope bearing the *nom de plume*, such envelope not to be opened until the Judges have made their awards, and at a meeting of the Committee. Where a Committee contributes more than one essay the same *nom de plume* to be used for each essay, and all essays to be written on white paper. The adjudicators will, in accordance with the express wish of the generous donor of the prizes, be instructed to pay due consideration in making their awards to neatness of handwriting, correctness of spelling, and accuracy of grammar, as well as to the information contained in the essays. Should the prizes in one or more classes not be awarded, the adjudicators will be empowered to award extra prizes in other classes, provided the essays are deserving

of the awards. Competent Judges will be appointed to adjudicate upon the essays. The prizes will be distributed at the annual dinner of the Association at the close of the session.

Class 1.—The selection and cultivation of hardy herbaceous and alpine plants. First prize, £2; second prize, £1 10s.; third prize, £1.

Class 2.—The best essays on any horticultural subject, at the discretion of the competitors. First prize, £2; second prize, £1 10s.; third prize, £1.

Class 3.—The best reports of the work of the session. The prizes in this class will consist of suitable books on horticultural subjects, to the value of £2—viz., first prize, £1; second prize, 12s. 6d.; third prize, 7s. 6d.

MANNERS AND CUSTOMS—A CATALOGUE COMMENTARY.

ON looking over a good collection of Roses a keen observer, even if he be a novice in Rose culture, cannot fail to be struck by the difference observable in what is called "the habit" of each sort, for there is almost endless variety in wood, leaves, thorns, strength, and manner of growth, apart from the blooms themselves. He would also probably notice a good many of what he would call "red" Roses, very much alike to his untrained eyes in general appearance, and he might wonder how they could all be distinguished apart. But if he would remember that a good shepherd can tell every member of a large flock of sheep by a diligent study of their faces, or even that any English-grown Apple can be correctly named at the office of this Journal, he will readily understand how a fairly representative bloom of any Rose can be accurately distinguished by a thoroughly expert rosarian.

Descriptions of the different varieties of Roses are to be found in the catalogues issued by growers for sale, and these (like the Roses themselves) will be found to be of different sorts—from the one deficient in descriptive power, which copies verbatim from another of reputation (and might well do worse) to the one which suffers from a superabundance of originality, and repeats a list of H.P.'s with entirely different descriptions on the very next page. A good many of these catalogues have full and for the most part good descriptions of the different varieties; but the colours of some sorts, especially of Teas, are very difficult to place before the eyes of ordinary readers in language that they will clearly understand, for some are naturally variable in their tints and others come much fuller in colour when grown strongly.

The novice student of these seductive pamphlets will require only a little knowledge of human nature to enable him to take a fair discount off the description given by the raiser himself of any one sort; and he may possibly, the following summer, be inclined sometimes to agree with those medical authorities who state that many people are colour-blind without being aware of their infirmity; but at any rate he will find it advantageous to be acquainted with some slight vagaries in catalogue-English which custom has sanctioned. In this language "medium-sized" means "small," and "pretty" generally implies the same. In growth "moderate" means weakly, "free" describes a plant rather weakly but branching, and "vigorous" stands for ordinary growth. A "good pot Rose" would probably show that it would not stand bad weather, a "nearly full" one shows an eye, and one would probably be doing no injustice in supposing that a Rose which is "good when caught right" is bad as a rule.

These remarks are not meant as a sneer at the catalogues and descriptions of our professional rosarians. Some of these are most carefully and laboriously compiled from a long and wide-spread knowledge of the various sorts, and, especially in the account of colours (which is naturally the principal part of their descriptions, and with which, as a rule, I shall not meddle), are certainly much better than anything of the sort that I could do. But it is a matter of common knowledge how unwise it is for a beginner to select his sorts from those blooms which take his fancy at an exhibition; and there are also drawbacks to the cultivation of a good many of the show varieties, which we cannot expect to find noted in catalogues for sale. For, among Roses, there are a great many "little ways" belonging to the different tribes, families, and individuals, and I would like to point out some of these for the guidance of novices who may be thinking of purchasing Roses for planting, for many an otherwise excellent Rose has a nasty custom of doing this or that or the other, which just prevents its being as good as it might be.

I propose going through an ordinary list of Roses, taking, not every one grown (I had a catalogue sent me the other day from a continental firm containing 1909 different varieties!), but most of the best known, following the N.R.S. catalogue in the main, mentioning only those which I have grown myself, and taking particular notice of those which have especial manners or customs. Besides private habits, either good or bad, of their own, Roses may be faulty in any of the following points:—An unhealthy constitution, weakness of growth, deficiency of foliage, special tendency to mildew or orange fungus, liability to be stained, gummed, or rotted by rain, or burnt by the sun, or to "come" badly, malformed, quartered, or divided, deficiency in stoutness and

smoothness of petal, fulness of centre, shape, colour, lasting qualities and size, a lack of freedom of bloom, or of good qualities in the autumn; and in Teas, besides a much increased impatience of rain, there is the peculiar fault of several, and, alas! some of the best, of not bringing blooms to full perfection when grown as dwarf plants. We know, however, that many Roses behave very differently according to the soil, the climate, the situation, and the treatment; and I hope, therefore, that any readers of the Journal who do not agree with my descriptions will write and say so, that we may have a better knowledge of the actual capabilities of the several varieties.

HYBRID PERPETUALS.

Abel Carrière (Verdier, 1875).—Of uncertain growth. Often makes strong secondary shoots, yet refuses to grow strong in the spring. Foliage second-rate; rather liable to mildew and orange fungus, but can stand a little rain. Often "comes" bad; not divided, but malformed, and "anyhow;" a small per-centage only of the blooms generally arrive at perfection. Not particularly good in petal; but the shape, partly imbricated, is good when you get it. Beautiful colour, among the darkest; a fair bloom to last, and not of the largest size. Like many of the dark Roses, it requires hot dull dry weather, for sun will cause the colour to "burn"—i.e., turn brown, and rain is more or less hurtful to all Roses. Not good as a free bloomer or as an autumnal Rose.

Abel Grand (Damaizin, 1865).—A useful garden Rose of very strong stiff hardy growth and fine foliage. Not liable to mildew or to suffer much from rain. Flat open shape, soon becoming weak in the centre; thin petals, not lasting, good size, strong of constitution, and will do well in lightish soil; very good in freedom of bloom and as an autumnal. Has "sported" once or twice. "Bessie Johnson" is identical, except that the colour is lighter.

Alfred Colomb (Lacharme, 1865).—Fine growth and foliage in good soil, but not on poor or light land. Not very liable to mildew, and can stand some rain. Generally comes good, but occasionally "divided." (I ought perhaps here to mention that the term "divided" is used when a rift appears in the outline of the centre or point. This seriously mars the bloom to a florist's eye, and from a show point of view. No "dressing" can counteract it, or so fold the petals as to hide it. In the worst cases four such rifts appear, and the bloom is then said to be "quartered.") A fine typical shape, what the N.R.S. catalogue calls "globular, high centre," which is a good description of this particular Rose in its perfection; extremely good in petal, centre, size, lasting qualities and colour. A first-class show Rose, late, fragrant, free in bloom, and good as an autumnal, with clean, smooth-skinned, handsome wood, striking well as a cutting. The flowers are often very like Marie Baumann, though the wood and habit of the plants are very different. Benoit Comte and Marshal P. Wilder are also similar in bloom, though the foliage of the former is very distinct. Comtesse de Casteja (Margottin, 1882), which I have not personally grown, is the only seedling of this fine Rose that I know.

Alfred K. Williams (Schwartz, 1877).—Makes long strong shoots as a maiden or as a cut-back at times on good soil, but has not a strong constitution. Thorny, with good foliage, liable to mildew, but will stand some rain. A Rose of great reputation, because the blooms nearly always come perfect, forming first-class examples of the popular "imbricated" shape—(i.e., something after the form of a Camellia). Not a very good one to last, or of the largest size, but prominent as a show Rose. Cannot be called first-class as a free bloomer, but is pretty good as an autumnal. The plants are not hardy or long-lived, and fresh ones should be budded every year, as though some do well as cutbacks, maidens are more to be depended upon. Grand Mogul is said to be a seedling from this beautiful Rose.

Annie Laxton (Laxton, 1869).—A good hardy garden Rose, with good growth, very fine foliage, and strong constitution. Not liable to mildew or much injured by rain. Useful as an early one, a free bloomer and fair autumnal. The blooms are of fair size, but not often of a good regular shape, and the petals are somewhat thin.—W. R. RAILLEM.

(To be continued.)

BULLFINCHES.

If "J. T. E." (page 476) expects to catch bullfinches now on the trap-cage principle, I am afraid he will be disappointed, as I have only caught one in a fortnight, making a total of thirty-eight in a few weeks. Now they pay very little attention to the call of a decoy, and every week they will become more careless. If I were inclined to catch more I would use birdlime, but this, to a certain extent, means turning out with a call bird and a stock-cage to put fresh caught birds in, as described by me before.

In the extract printed from the *Worcester Herald* (page 459), Miss Ormerod, in reply to some of my remarks in a previous issue of that journal, appears to doubt to some extent the mischief these birds do by the following remark:—"I do not myself feel so sure as some writers that the bullfinch is so very injurious, and would much like that, before condemning him, a careful post-mortem of contents of stomachs of a few specimens should be made, to see whether the abstracted buds had, or had not, a maggot within them." I assure that lady, and all readers, that I am not in the habit of writing anything that I cannot substantiate, and I have watched these birds most carefully in their work

of destruction, and that they take every bloom bud within reach indiscriminately, and that a single bird will nip out twenty-five buds per minute (by my watch), discarding all outside, and swallow only the flower and fruit in embryo. The stomachs I have frequently examined with a magnifying glass, and have one lying before me now that I have used as an illustration at many lectures on horticulturists' enemies. If time and space permitted, I should have been pleased to have made a few remarks *re* "Caterpillar Plague" (page 459). I have taken thousands of the moths on grease-bands, and other ways; but I have patented what I consider an improvement on any method yet invented in stopping the moths and other pests to fruit growers.—J. HIAM, *Astwood Bank*.

NORTH AMERICAN SHRUBS.

THE first warm days of April invite us to the woods in search of the *Arbutus*; a glimpse of green rewards our expectant eyes, and we move the leaves carefully from the gnarled and twisted Oak roots, only to find tiny clusters of buds with no gleam of pearly white or rosy pink among the glossy leaves; we turn away disappointed and look down the hillside toward the meadow, and lo, a bush all covered in creamy, dainty blossoms greets us. We step carefully over the patches of *Hepatica* and *Erythronium* just peeping out of the moist clayey soil, and try to break off the slender, grey, smooth twigs, and we twist and pull and bend in vain; truly it might be called rubber instead of Leather Wood, this fairy blossomed *Dirca*, the earliest flower of our New England woods. The *Houstonia* only is brave enough to lift her pale blue face in the warmest and sunniest meadows, and the *Saxifrage* is trying to bloom in the sunny crevices of the rocks. But the sun mounts higher, day by day, and the *Andromeda*, in the swamps, hangs out her thousands of pearly bells to lure the bees, and the Alder tags shake their golden pollen on the pale green sphagnum at their roots. Here and there, in the woods and in the thickets along the river banks, the snowy flowers of the *Amelanchier*, or *Shadblow*, unfold in a night, the petals of one species faintly tinted with pink. Hardly a leaf has yet unfolded, but one by one the delicate translucent petals float off seemingly like snow-flakes through the air, and the bush stands forth clad in emerald green, many a leaf with crimson veins and margins which disappear as it attains its full size.

The warm days of May come swiftly, and the beautiful flowering *Dogwood*, *Cornus florida*, flings forth its banners to the sunshine, every great, white, four-petalled involucre looking straight upward as if proud of its clusters of greenish yellow flowers, which no one notices; irregular, of course, it is, whoever saw one that did not have two large and two smaller petals, making the blossom oval instead of round? Then that brown, shrivelled spot, with a dash of crimson in it that is always on the margin of each petal, and is not an imperfection, as it seems, but an individuality. In New England we have *Cornus alternifolia*, with its loose cymes of pale buff flowers; *Cornus sericea*, with dull purplish branches, and young shoots of dark red; *Cornus paniculata*, with grey bark and flowers in cone-like cymes and nearly white; *Cornus stolonifera*, which sends out horizontal branches, and whose flat cymes of yellowish flowers are in pleasing contrast to the velvety green, full grown leaves. These species of *Cornus* are all hardy, bear transplanting well, and without exception very ornamental.

Scattered about on the hillsides, and more especially towards the coast, throughout New England, are the *Barberry* bushes, every leaf bristling with sharp points, but fragrant drooping clusters of yellow flowers in June, succeeded by oblong berries in September, which good housekeepers make into jelly. Another shrub, which is known by its glossy, very dark green leaves, is the *Prickly Ash*. Its inconspicuous greenish flowers appear about the 1st of May, before the leaves. Its numerous brown prickles make it well adapted for hedges. It grows rapidly, and its roots penetrate the ground for a long distance.

Everyone knows the common *Sumac*, with its yellowish-green panicles of flowers in June, and its cone-like heads of scarlet berries in early autumn. One of our largest shrubs, growing when standing alone to a height of 20 or more feet, its greyish, woolly-looking branches crowned with its spreading, palm-like mass of foliage, bright light green in summer, and blazing scarlet in autumn, making it always conspicuous, especially when growing in masses, as it generally does. Here and there, in patches in the swamps, grows the shrub called *Poison Sumac*, with its disagreeable odour, and easily distinguished by its red, wingless petioles, and its smooth, greenish-yellow berries. *Rhus Toxicodendron*, or *Poison Oak*, is a weak shrub with brownish grey berries, and is not noticed as often as *Rhus radicans*, or the climbing species, which is usually called *Poison Ivy*, and is very often taken for *Virginia Creeper*, but from which it may be distinguished by its three leaflets, the lower one nearly always differing from the other two; its leaves are dark and shining, frequently tinged with red, and in early autumn it takes on very brilliant hues of gold and flame; its berries are white; its small, greenish flowers appear in May.

In hilly woods we sometimes find the *Maple Bush*, *Acer spicatum*, with its pretty clusters of greenish flowers, light grey bark, and coarse, sharply pointed leaves, which are both three and five lobed in the same bush. We seldom notice the twining shrub or climber called *Climbing Bittersweet*, *Celastrus scandens*, during the summer, as it is generally hidden amongst the foliage of the trees in the edges of the woods, but after frost its clusters of scarlet seed vessels, nestled in the three-sepalled, orange calyx, are quickly seen and gathered to brighten the Christmas

evergreens; they retain their colour, grow hard and firm, and, if kept from insects, will keep for a long time.

One of our smallest shrubs is the pretty little *Ceanothus*, or Jersey Tea; it is found almost everywhere in New England, and in the West. In June every little branch is terminated with a dense panicle of minute white flowers, the branches growing from the axils of the leaves, which are soft and downy on the under side, and are said to have been used for tea during the Revolution; its large, red root is used for colouring.

The far-famed English Ivy is not hardy in New England, except, perhaps, in sheltered situations near the coast, but wherever it can gain a foothold it grows rapidly. The American Ivy, or Virginia Creeper, *Ampelopsis quinquefolia*, flaunts its rank growth from cathedral walls and stately churches, making them veritable poems in stone, clings lovingly to the dear old homesteads, fringes the small windows of the cottage in the outskirts, drapes the mossy rails of the old farm fences, catches the sunshine through the golden days of summer to throw it forth from its leaves in autumn in great splashes of colour, rivalling the most brilliant sunset. The dusky, purple berries hang in clusters to tempt the birds who pick them, one by one, till only the rosy pink pedicels are left to drop off after the leaves.—FLORENCE I. W. BURNHAM (in *Vick's Magazine*.)

(To be continued.)

QUEEN WASPS.

ALTHOUGH I have not secured queen wasps in the manner referred to by Mr. W. Strugnell (page 463), I have secured some thousands from having an opportunity of building next spring by taking every nest known of in the neighbourhood up to the time of the breaking up and distribution of the colonies in the autumn. I have one nest of *Vespa germanica* I dug out very carefully, which is quite complete, and I consider there would have been at least 250 queens to look out for snug winter quarters. The bulk of these appear to be alive, and quietly taking their six-months nap under my control instead of starting new colonies.—J. HIAM.

AT page 463 of this Journal Mr. Strugnell states some experience in securing queen wasps between the wall and window frame of a fruit room, and asks if any others have secured them in a similar manner. I have frequently found queen wasps concealed between the walls and frames of windows, but by far the greater number will be found between the layers of timber when in stacks, or the bark of trees, nested in one another, but with space between sufficient for wasps to creep into for the purpose of hibernating. "The low buzzing sound" heard by Mr. Strugnell has interested me. I was not aware that wasps, or any other hibernating creature, emitted sounds when in a state of hibernation. If this is so, then it strengthens "A Hallamshire Bee-keeper's" opinion on that question, and bees may after all be hibernating, although we hear them huzzing aloud during the cold of winter. I should be glad if a few more facts about this were forthcoming, so that I might be induced to turn my attention to the subject.—W. T. Blantyre.

ORCHID NAMING.

IT is generally understood that the Royal Horticultural Society is formulating a system of Orchid naming that is intended to remove some of the inconsistencies at present existing. That being so, why is it not made known to all the Fellows of the Society interested in the matter? as a subject of such importance cannot be too widely discussed. Any decisions arrived at from a partial consideration of the matter, or without consulting the large body of Orchid growers, will be certain to give great dissatisfaction and prove extremely discreditable to the R.H.S. I would suggest that forms be sent out to the Fellows in the same way as for the recent *Chrysanthemum* Centenary, or as is being done now to procure information respecting the effects of fogs. From returns thus obtained a good idea of the general feeling would be secured. The project is a good one, but will be spoiled by hasty or too restricted attempts at settlement.—AMATEUR F.R.H.S.

THE HALL AND FRASER FUND.

MR. FRED. HORSMAN of Colchester sends the following additional list of subscriptions received or promised for the above fund. Messrs. Sander & Co., £5; Mr. John Seden, 10s. 6d.; Mr. John Cowan, £1 1s.; Mr. Howell, 10s. 6d.; Mr. E. Jenkins, 5s.; Mr. W. White (Dorking), 5s.; Chas. Toope, Esq., £1. Collected by Mr. H. B. Smyth's stand at the National Chrysanthemum Show:—Mr. W. Holmes, 5s.; Mr. W. Howe, 2s. 6d.; Mr. Crute, 2s. 6d.; Mr. F. Wilson, 2s. 6d.; G. Mayor, Esq., £2 2s.; Mr. J. Roberts,

2s. 6d.; J. H. W., 1s.; Mr. R. Davis, 5s.; Mr. Don, 2s.; Mr. Ballantine, 2s. 6d.; Mr. S. Deards, 2s. 6d.; Mr. Brangwin, 2s.; Mr. W. May, 2s.; Mr. J. Reynolds, 2s.; A. B., 2s.; J. M., 2s.; Mr. Jos. Arnold, 2s. 6d.—£4 2s. 6d.

A meeting of the Committee having in hand the organisation of this fund was held at Messrs. Protheroe & Morris's Rooms on the 29th ult., Mr. Harry J. Veitch presiding. The Hon. Secretary, Mr. Fred Horsman, stated that the total amount received and promised up to that date was about £410, and it was unanimously resolved that the list should be closed on December 12th, by which time it is desirable that all promised subscriptions should be sent in. The Committee will meet again on the 13th to determine the disposal of the fund.

DENDROBIUM AUREUM.

A FINE specimen of the above *Dendrobium* may now be seen flowering in the Victoria House collection. The plant is growing in a 10-inch basket, and is bearing 179 flowers, some of the pseudobulbs having twenty blooms. The sepals and petals are cream coloured or yellow; the lip has a velvety disc, golden yellow streaked and veined with crimson lines, recurved at the tip. It is not one of the most showy *Dendrobiums*, but should be grown on account of its sweet scented flowers, the perfume resembling that of Violets combined with Primroses. The same plant carried eighty-six flowers last year.—H. COOPER.

THE SHELL-BARK HICKORY.

THE Hickory is purely an American tree. The eight species which are known all belong to the southern half of the North American continent, with the headquarters of the genus, as represented by the greatest number of species in any one locality, in the valley of the Red River in Arkansas, with one species pushing far south along the Mexican Sierra Madre. No other country or region of the earth can boast of an indigenous Hickory tree, although it is quite within the bounds of possibility that one, and perhaps several species may still be found in the unexplored mountain districts of central China, so similar are the floras of our eastern States and of eastern Asia in actual composition, and so closely related in their descent from remote common ancestors. The Hickories, at least some of the species, are among the most valuable trees in the world. There has never been a boy or girl brought up in any part of the country east of the Missouri River who has not early learned the value of the Pecan, or the Hickory Nut, or the Mockernut; and the wood which some of these trees yield has no equal, and certainly no superior, for certain purposes. There is no wood at once so tough and strong and true. It is the Hickory wood in its handle which has carried the American axe round the world, driving, wherever it is known, all other axes out of the market; and it has made possible those light carriages, which, in turn have made possible the American trotting horse, one of the marvels of these modern times, and probably the best example of what can be accomplished, by careful breeding and persistent selection, in the development of domestic animals for a special purpose. No other tree is known whose wood is tough enough and strong enough to stand the strain imposed upon the American trotting-sulky, and without the modern sulky and its heavier forerunner, neither breeding nor training could have produced that race of horses which every American looks upon in his heart of hearts with joy and admiration. As a nation we owe much to the Hickory tree, and we have good and just reason for being proud of it. It is a tree known to many people; next to the Oak and the Pine, more Americans know the Hickory tree when they see it than any other of our trees. That is, they know generally the Hickory without distinguishing the different species, which is hardly surprising, since botanists themselves are often perplexed over questions concerning the proper limitations of these species. Nor are these questions ever likely to be settled quite satisfactorily, for it is probable that several of the species are inclined to hybridise one with another, and so produce those individuals of doubtful characters which are the despair of people who expect to be able to fit exactly every plant they encounter with the printed description of it in some book.

The Shell-bark Hickory is considered generally the most valuable of the genus. The nuts, of course, are not esteemed as highly as Pecans, and they are, perhaps, rather inferior to and considerably smaller than those of a western representative of the genus (*Hickorius sulcatus*), the wood of which is equal to that of the Shell-bark. Still, the Shell-bark, perhaps, is the tree which people have in mind generally when they think or speak of a Hickory tree; and the peculiarity of the bark which separates into great thick, loose scales, gives to this tree a distinctive appearance, which makes it easily known and recognised.

The Shell-bark, as it is now seen in the eastern States, is generally an obconical, square-topped tree, with rather small branches, produced low down on the trunk. Such trees have grown generally since the land was first cleared for settlement and agriculture, and there are not now many people living here at the east who, unless they know the forests of the Mississippi Valley, and more especially those found on the higher Alleghany Mountains, have an idea of what a large Hickory tree is, growing as it grew naturally before the white man disturbed and changed the natural condition of this country. The Shell-barks in

southern Indiana, Mr. Ridgway notes ("Proc. U. S. Nat. Mus.," 1882, 77), are sometimes 150 feet high, with trunks 4 or 5 feet in diameter, and bare of limbs for 70 or 80 feet; and even larger trees can be found in the western and still almost untouched forests of eastern Tennessee and western North Carolina. But these large trees are doomed, and before many more years have passed every Hickory tree of sufficient size and proper quality will have been sacrificed to supply the ever increasing demands which the industries of men make on this tree. The area of the region in which the Hickory grows to perfection is really small in comparison with the demand for it; and when no substitute can be found for a particular wood it must in time be exterminated, however abundant the natural supply, unless measures are taken to increase and perpetuate it artificially. And it would appear that of all our trees the Hickory is the one which should be planted wherever suitable land can be spared for it; and it should be protected and cherished, in view of the ever-increasing demands the world is making and must continue to make on this tree.—(*The American Garden*.)

CHRYSANTHEMUM SHOWS.

ALTHOUGH we have been enabled by the kindness of numerous correspondents in various parts of the country, in addition to our own staff, to give the reports of over sixty Exhibitions, readers still remind us that some have been omitted, and local newspaper reports are sent, which we are unable to utilise. To all who have assisted by sending brief original notes we express our thanks. Successful displays have been held at Wimbledon (Surrey), Balham, West Hartlepool, and the following:—

CARDIFF.

THE third annual Show of the Cardiff and District Chrysanthemum Society was held in the Park Hall on Tuesday and Wednesday in last week. The Mayor of the town, Mr. Alderman Saunders, opened the Exhibition with a brief speech. The large hall was well filled with the various exhibits, many of which were of more than usual merit, and the Show, on the whole, was a decided advance on the two former efforts. The entries in the cut bloom classes were numerous and the competition was close, especially in the open classes. In the amateurs' class the competition was also very close, and some magnificent blooms were staged. The class for cottagers also brought to notice some very praiseworthy efforts. A strong feature in connection with this Show were the groups, which in the open class occupied spaces of 80 square feet and in the amateurs' 60 square feet. In both classes the exhibits were extremely good, and the two classes formed banks along the centre of the hall, the whole forming a magnificent display of bloom. Fruit and vegetables also were numerous shown, the entries for Apples being especially large, and some splendid dishes were staged. There were also classes for Ferns, Bouvardias, Cyclamen, Primulas, Selaginellas, and plants for table decoration, all of which added something towards making a show.

Cut Blooms.—Twenty-four distinct named varieties, Mr. W. Treseder, nurseryman, Cardiff, was first; Mr. W. J. Ireland, Singleton, Swansea, second; and Mr. C. H. Williams, Roath Court, third. Twelve incurved, Mr. Ireland first and Mr. W. Waldron, Llandaff (gardener, Mr. H. Rex), second. Twelve Japanese, Mr. Ireland was again first with a magnificent dozen. For groups arranged for effect Mr. W. Treseder was first, Marquis of Bute (gardener, Mr. A. Pettigrew) second, and Mr. C. H. Williams (gardener, Mr. A. Bishop) third. In the classes for plants Colonel Hill, C.B., M.P., Marquis of Bute, and Mr. C. H. Williams were the principal winners, the latter exhibitor showing a splendid example of Pompon Snowdrop.

Fruit.—Collection of five dishes. First, Colonel Turberville (gardener, Mr. G. Hawkins); second, Mr. H. W. Thompson, Llandaff (gardener, Mr. Ryder). For twelve Apples, dessert, first Colonel Turberville, second Mr. C. Waldron, third Mr. G. M. Treharne. Twelve Apples, culinary, first Mr. C. H. Jenkins, second Marquis of Bute, third Colonel Turberville. Twelve Pears, dessert, first Colonel Turberville, second Marquis of Bute, third Mrs. Kelly. Twelve Pears, culinary, first Colonel Turberville, second Marquis of Bute, third Mr. Ireland. For a collection of Apples, twelve dishes, first Mr. C. E. Jenkins, second Mr. W. H. Thompson, third Mr. Ireland. Collection of Pears, six dishes, first Marquis of Bute, second Mrs. Kelly. Collection of vegetables, six varieties, first Mr. G. M. Trenarne, second General Lee, Dinas Powis, third Marquis of Bute. Special prize, offered by Messrs. Wood & Sons, and grown by their manures, stand of twelve Chrysanthemum blooms, first (silver medal) Mr. W. H. Thompson. Wreath, not to exceed 20 inches, first Mr. Phelps, Cardiff; second Mr. Treseder. Cross, first Messrs. Perkins and Son, Coventry, who were also first for the best hand bouquet and gentlemen's buttonholes.

SUDBURY.

THE autumn Exhibition of this Society was held at the Corn Exchange, Sudbury, recently, and for a provincial show was a really good display. The schedule comprised seventy-two classes, a great many of which were solely for fruit and vegetables, and as might be imagined, being in the midst of an agricultural district, these were shown of high excellence. The ladies' classes for bouquets, epergnes, and sprays was most keenly contested, and formed a most interesting feature in itself, some sixty different exhibits being staged in the six classes set apart for them, and further interest was thrown into these classes that they were judged by ladies of rank and high social position. Several very

neat groups were shown both by professionals and amateurs, the first prize group being exhibited by Mr. Dance, gardener to Mrs. Lowe, Gosfield, and was remarkable for their exceeding dwarf habit, the tallest being scarcely 3 feet high at the back, while the front was only 18 inches; yet these very dwarf plants carried good fresh flowers, and the colours very well arranged, perhaps a little too like a mould, they were so evenly placed. The collection from the garden of Col. Burke took second honours, while in the amateur groups Mr. A. Berry and Dr. Holden shared the honours, with capital examples of the well known varieties. What a marked improvement there is now throughout the country in both growing and grouping Chrysanthemums than formerly. In almost every exhibition it has become a leading feature. Several fine groups of foliage plants were staged, the best arrangement being contributed by Mr. Mitchell, who had some good Crotons, Poinsettias, Heaths, Eranthemums, and Ferns. This was indeed a very tasteful display. Mr. Cundy was a good second.

In the several cut bloom classes Mr. Dance, gardener to Mrs. Lowe, was almost invariably placed first for highly meritorious collections, showing that his productions were ahead of the other exhibitors, and that he possesses the spirit and ability of a good grower. Other successful exhibitors were Mr. Cundy, Sir W. Parker, Col. Burke, Mr. Mitchell, Miss Faulkner, and Mr. Gentry. In the amateur cut bloom classes Dr. Holden, Dr. Turner, and Mr. A. Berry were the principal winners. Primulas were numerous staged, and the collections contained several beautiful strains. Fruit was also good, especially Apples and Pears, most of which was highly coloured. Vegetables throughout were grand, whether exhibited by professional gardeners, amateurs, or cottagers, and taking the Show collectively it was a most interesting Exhibition, and during the afternoon well patronised by the *élite* of the neighbourhood. During the evening, when the price was lower, it was crowded; there was no approaching the table decorations, bouquets, &c. Mr. De la Cour, the Hon. Secretary, laboured hard to supply the many wants required, ably assisted by Dr. Holden and others of the executive. We should like to see another year the name and address of the gardener on the prizecards. This would give more interest to strangers.

BEVERLEY.—NOVEMBER 27TH.

THIS Exhibition was held on the above date in the New Gymnasium Hall, which was recently opened with a grand bazaar. The building is large and lofty, and admirably adapted for large public meetings, flower shows, &c. This was the seventh annual Exhibition of the Society, and the President, Vice-Presidents, and Committee, in conjunction with a hard-working Treasurer and Secretary, are to be congratulated on the success of their labour, for notwithstanding the sudden outburst of almost Arctic weather, and the late date of the Show, there was a goodly array of exhibits, and in many of the classes the competition was exceptionally keen. In the open classes for plants, fine, large, well-flowered, and nicely trained plants (though a trifle *passé*) were exhibited by Mr. T. Smith of Norwood Nursery, Beverley; T. Crust, Esq., St. Mary's, Beverley; Mr. H. Taylor, Newland Nursery, Beverley; Mr. R. Thirk, Beverley; and Mr. G. Hancock, Beverley.

In the open classes for cut blooms Mr. T. Smith was first for twenty-four (twelve incurved and twelve Japanese), having good fresh blooms, well set up, of both sections. Mr. H. Taylor was a good second. In the classes for twelve cut blooms, distinct varieties, J. A. Hudson, Esq., J.P., Longcroft, Beverley, won with a capital lot, being closely followed by Colonel Hodgson, Westwood Hall, Beverley. In the smaller classes, J. A. Hudson, Esq., J.P., almost "swept the deck" of premier honours, although the stands of both Col. Stracey-Clitheroe, J.P., of Hotham Hall, and Col. Hodgson, were in many cases very close on the heels of the winner. The wreath competition (Chrysanthemums only) was an excellent class both in number and merit, Mr. G. Cottam, nurseryman, Cottingham, Hull, taking the coveted position. In bouquets, Messrs. Taylor of Newland and Cottam of Cottingham were far ahead of other exhibitors.

In the fruit classes, Col. Clitheroe, J.P., scored both firsts for black and white Grapes with bunches of Gros Colman and White Tokay, the first-named bunches having large berries, good colour, and capital bloom. W. F. Wrangham, Esq., J.P., Hotham House, was a good second in both classes. The last-named gentleman also took the principal prizes for Apples and Pears with exhibits of large size and good quality. Mr. H. Adams of Beverley was a successful exhibitor in those classes. The Judges were Mr. Charles Lawton, gardener to Colonel W. H. Harrison Broadley, Welton House, Brough, East Yorks; and Mr. R. Sturdy, gardener to Charles Sykes, Esq., West Ella, Hull. The Hon. Sec. of the Society is Mr. Chas. Wellbourn, who, whilst being thoroughly energetic in carrying out his duties, was also most courteous to all.

BIRKENHEAD AND WIRRAL.

THE above Society held their third annual Show in the Town Hall, and the Show was a success, considering it was a wet day. The Grapes were good, as also were cut blooms, and in the fruit classes there was a keen competition.

Cut Blooms.—In the open class for twenty-four incurved, in not less than eighteen varieties, Mr. G. Burden, gardener to G. Cockburn, Esq., Lingdale Lodge, Cloughton, was first with even blooms of good substance and bright in colour. The stand comprised the following varieties:—Empress of India (2), Queen of England (2), Lord Alcester (2), Alfred Salter (2), Princess of Wales (2), Miss M. A. Haggas (2), John Salter, Princess of Teck, Miss Violet Tomlin, Emily Dale, Mrs. Heale, Jardin des Plantes, Jeanne d'Arc, Lady Hardinge, Sir Stafford

Carcy, Princess Beatrice, Refulgens, and Golden Empress. Mr. J. Wilson, gardener to J. E. Reynolds, Esq., West Derby, Liverpool, was a good second. Mr. G. Malcomb, gardener to J. Tomkinson, Esq., Tarporley, Cheshire, was third. In the open class for twenty-four Japanese, in not less than eighteen varieties, Mr. G. Burden was again first, showing good examples of the following:—Boule d'Or (2), Stanstead White (2), Avalanche (2) very fine, Sunflower (2), Ralph Brocklebank (2), Madame C. Audiguier (2), Pelican, Belle Paule, Thomas Stephenson, M. Bernard, Madame Baco, Sarah Owen, Marguerite Marrouch, Mr. Gardiner, Jeanne Délaux, Madame J. Laing, Meg Merrilies, Edwin Molyneux—a good bright collection. Mr. J. Wilson was second with very fine examples of Balmoreau; Mr. G. Malcomb third with smaller but fresh flowers. In the open class for twelve incurved Mr. G. Lyon, gardener to J. H. Kenion, Esq., Egerton Park, Rock Ferry, was a good first; Mr. T. Winkworth, gardener to R. Brocklebank, Esq., Childwall Hall, Liverpool, second; Mr. T. Rawson, gardener to H. R. Rodgers, Esq., third. In the open class for twelve Japanese, Mr. E. Broadey, gardener to H. L. Jones, Esq., Horton Grange, was well first; Mr. C. Waring, gardener to Mrs. Aitken, Princess Park, Liverpool, a close second; and Mr. H. Holford, gardener to Mrs. Cornelius, Aigburth, Liverpool, third.

In the local classes the chief prizetakers were Mr. G. Burden, Mr. E. Broady, Mr. D. Mason, gardener to W. Bingham, Esq., Claughton, Mr. G. Lyon, Mr. Charles Smith, gardener to D. Wilson, Esq., Claughton, Mr. M. Clary, gardener to R. Hobson, Esq., Bromboro', Mr. T. Rawson, Mr. J. Hay, gardener to G. Irvin, Esq., Mr. J. Brown, gardener to G. Webster, Esq., Upton, Mr. T. Williams, Mr. T. Pink, gardener to J. J. Sealby, Esq., Mr. Smith, gardener to T. L. Pelling, Esq., Oxtou.

In the fruit classes (open) the leading exhibitors were Mr. J. Barker, gardener to G. Raynes, Esq., Rock Park; Mr. J. Bounds, gardener to A. L. Jones, Esq., Aighurth, Liverpool; Mr. Hannagan, gardener to R. C. Naylor, Esq., Horton Hall; Mr. F. Ferguson, gardener to Mrs. Paterson, Rock Ferry; Mr. R. Brownbill, gardener to G. Fowler, Esq., Rock Ferry; Mr. G. Butler, gardener to T. Drysdale, Esq., Mossley Hall, Liverpool; Mr. S. Winkworth; Mr. M. Quirk, gardener to W. Porter, Esq., Thingwall; Mr. G. Worker, Mollington; Mr. J. Salisbury, gardener to E. Osborne, Esq., Newton Chester; Rev. H. C. Sturges, Leominster; Mr. A. Williams, Leominster.

In other classes for miscellaneous plants the prizes were secured by Mr. W. Thomas, gardener to G. E. Grayson, Esq., Claughton; Mr. J. Richards, gardener to Mrs. Friend, Rock Park; Mr. J. Brown; Mr. S. E. Haines, gardener to M. Laird, Esq., Claughton; Mr. J. Grindley, gardener to J. Billington Esq., Wallissey; Mr. M. Quirk; Mr. A. Price, gardener to F. Jevons, Esq., Claughton; Mr. S. E. Haines. Of miscellaneous exhibits a good arrangement of plants around the orchestra came from Mr. Johnson, South Grove Nursery, and a grand collection of Apples from Messrs. Dickson, Chester. The success of the Show is due in a measure to the kindness of T. L. Pelling, Esq., the President, taking an active part in the management, and to the able Secretary, Mr. A. Haughton.

BARNSELY.

FROM its contiguity to the hills and moors of the Pennine range, and from the smoke of its collieries, coke ovens, glassworks, and other industries, the town has been dubbed not inaptly "Black and Bleak Barnsley," which is sufficiently indicative of conditions not the most favourable to horticultural pursuits: nevertheless the local "Paxton Society" and its numerous patrons by their energy and perseverance get together two exhibitions in the year of horticultural produce of which any town might feel proud. In September the working men make a grand display of cultivated vegetables. Again in November they deck their "People's Hall" with Chrysanthemums, and through the place in their thousands to admire, criticise, and add to their enthusiasm. This Chrysanthemum Show was the best ever held in Barnsley. On entering the room this was at once apparent both in the increased entries and the quality of the exhibits. In the open class for twenty-four cut blooms, twelve Japanese and twelve incurved, £5 and National certificate was offered for the first prize, which was keenly contested for by seven exhibitors, Mr. Daniels, Hallcroft, Mirfield, taking first position with high class heavy blooms as follows:—Incurved—Back row: Empress of India, Queen of England, Lord Alcester, Alfred Salter. Middle row: Nil Desperandum, Golden Empress, Lord Wolseley, Emily Dale. Front row: Miss M. A. Haggas, Mrs. Shipman, Mr. Bunn, Princess of Wales. Japanese—Back row: Meg Merrilies, Boule d'Or, Madame C. Audiguier, Ralph Brocklebank. Middle row: Val d'Andorre, Stanstead White, Sunflower, R. Ballantine. Front row: Madame Baco, Florence Percy, J. Délaux, Avalanche. Every bloom of the above was remarkably well timed and at its best. Mr. T. B. Morton, Darlington, took second prize, showing fine examples, Lord Alcester, Princess of Wales, Lady Hardinge, Mrs. Heale, Empress Eugénie, &c., amongst the incurved. Belle Paule, Stanstead White, Condor, Etoile de Lyon were very conspicuous amongst his Japanese. Some of the incurved flowers being too young, with undeveloped centres detracted somewhat from the chances of this stand. Mr. Leadbetter, gardener to A. Wilson, Esq., Tranby Croft, was placed third, whose stand included fine examples of Japanese, but many were too old. In the class for twelve reflexed Mr. Morton was first, Mr. Daniels second, G. Burnley, Esq., Birthwaite Hall, third. Twelve Anemones.—Mr. Daniels first, Mr. Morton second, C. Simpson, Esq. (Mr. Kitchil, gardener), Ackworth, third. Bouquets.—Mr. Daniels first, Mr. B. Asquith, Barnsley, second, J. Dunk, Esq., Worsbro', third. Fruit.—Grapes, Black.—Mr. T. Kitchil first, Mr. G.

Hudson second, Mr. R. Sleightholm third. White Grapes.—Rev. W. Elmhirst first, Mr. T. Kitchil second.

In the local classes, Mr. Balanger was first for a well-arranged group of miscellaneous plants, Mr. Henshall, nurseryman, Barnsley, being second with a useful lot of decorative plants, but lacking colour somewhat. Groups of Chrysanthemums showed the necessity of more care in the details of arrangement. Mr. Henshall was well to the front, avoiding mistakes in this respect, and so won the first prize. W. Robinson, Esq., Barnsley, being placed second with fine plants carrying blooms of high quality, but faulty in arrangement towards the margin. In the smaller plant classes there was keen competition, the prizewinners being Messrs. Peel, Kenworthy, Goodyear, Tyas, Fever, Senior, Gratton, and Whitaker. For local class cut blooms, Messrs. Goodyear, Tyas, Balanger, Fever, Senior, and Peel.

PONTEFRAC.—NOVEMBER 28TH.

CONTRARY to what might have been expected, considering the lateness of the fixture and general earliness of Chrysanthemums this year, a bright, effective, and highly creditable Exhibition was provided in the Assembly Rooms of the famous old Yorkshire town on the date named. Several of the blooms had no doubt passed the zenith of their beauty, but it was surprising how many there were with which scarcely any fault could be found in that respect, while not a few were in all other respects excellent. In some of the cut bloom classes the competition was exceedingly keen; in the mixed classes the Japanese excelling in one, the incurved blooms in the other, and the true relative values of the collections could only be determined by the most careful point judging. This, however, was not the case in the open class of thirty-six blooms, in which Mr. T. B. Morton, Darlington, took a distinct lead with handsome and well staged examples in both sections. The stands also contained the two premier blooms—a beautiful Lord Alcester, and a fine example of the new and bright red Japanese W. W. Coles. The same variety has been exhibited under the name of W. W. Coules, and whichever rendering may be correct the bloom in question must be recorded as one of the most effective of the season. Condor and M. E. A. Carrière, both white, were also exceptionally fine. Among other new varieties exhibited by Mr. Morton, Beauty of Castlewood was admired for its richness of colour; it is of the E. Molyneux type, and apparently quite distinct. Mr. W. Clough, Keighley, was second in the above class, his stands containing several remarkably good blooms.

The next important class was for twenty-four blooms in the two chief sections, the first prize being a silver cup, Mr. T. W. Tew of Carleton winning it in one of the keenest of contests, Mr. R. James of Bads-worth Hall being a dangerously close second. Mr. Tew also secured the leading position with twelve incurved blooms, and Mr. Jackson with twelve Japanese. Mr. C. H. Simpson of Ackworth exhibited well in the Chrysanthemum and other classes, winning several prizes. Bouquets, wreaths, sprays, and exhibits of that nature surpassed those seen at many greater shows, Messrs. J. & R. Calam, Wakefield, and Rev. G. Haslam, Brotherton, being the chief prizetakers.

The plants exhibited were generally such as are usually seen in conservatories, or not formally trained. There was room for improvement, and some of the exhibitors learned that the judges did not attach the greatest value to the largest plants in the largest pots, but recognised merit in culture as displayed by small plants with healthy foliage as well as fresh blooms. Groups, both of Chrysanthemums and miscellaneous plants, are usually good at Pontefract; and in the former section the first prize group of Mr. Wm. Bell, gardener to J. Rhodes, Esq., Syddale Hall, was highly meritorious, the plants being both well grown and tastefully arranged—one of the best groups of the year. Mr. W. Jackson, Ackworth, was the chief prizewinner in the miscellaneous class, with a neat creditable assortment. There was good competition in many other classes, which cannot be enumerated. Fruit was fairly well represented, and amateurs' collections of vegetables worthy of high praise. The district is famous for vegetables, and more particularly for Liquorice culture, many acres being devoted to the crops, which are said to be profitable.

The Exhibition was opened by the Mayor, Mr. Alderman Rhodes, the eighth year in which he has been elected to the high office; and Mr. Glover, the Secretary, with able and willing assistants Messrs. Sheen, Maddox, Hillahy, and others, worked assiduously in making the Show and proceedings agreeable to all.

BARTON-ON-HUMBER.

THE Barton and District Chrysanthemum Society held their second annual Show in the Oddfellows Hall on the 27th November, when there was a good display of cut blooms, especially in the open classes, and some excellently arranged groups, whilst the efforts of the ladies with bouquets and table decorations were highly meritorious. Open classes, twenty-four blooms, twelve incurved and twelve Japanese, distinct.—First, G. B. Guthrie, Esq., Waltham Hall (Mr. J. Walker, gardener); second, E. Smith Paull, Esq. Twelve incurved.—First, Mr. E. Smith; second, Mr. H. Taylor, Newland. Twelve Japanese.—First, G. A. Carr, Esq., Waltham Grove (gardener, Mr. W. Welton); second, Mr. E. Smith; third, Mr. H. Taylor. Twelve blooms, any variety.—First, Mr. E. Smith; second, G. A. Carr, Esq.; third, Mr. H. Taylor. Group of Chrysanthemums.—First, Mr. J. H. Crowder; second, Mr. W. Briggs; third, Mr. H. Kirkby. Six Chrysanthemums, distinct.—First, Mr. W. H. Upplehy, Bonby; second, Mr. J. Skelton. Best specimen plant.—First, Mr. C. J. H. Crowder; second, Mr. J. Skelton. Twelve Primulas.—First, Mr. C.

Leeson, Wrawhy; second, Mr. W. H. Uppley. Amateurs classes were well filled. Mr. Leadbetter, gardener to A. Wilson, Esq., Tranby Croft, Hull, acted as Judge.

FRUIT FORCING.

VINES.—*Houses Started Early in November.*—In the earliest house, whether the Vines are in pots or planted in borders, the temperature will need to be increased to 60° at night in mild weather, 55° in severe weather after the buds break, gradually increasing so as to have it 60° at night when the Vines are in leaf, 65° by day in severe weather, and 70° to 75° in mild weather, with moderate ventilation. The evaporation troughs need not as yet be charged with liquid manure, provided there are fermenting materials in the house, but if not the troughs should be filled with the drainings of the dung yard or stables, and cow hyres, avoiding, however, that of pigstyes or urinals. Failing those use guano, 1 lb. to 20 gallons of water, which is also suitable for watering Vines in pots, the water being applied at the temperature of the house. Tie up the Vines in position as soon as growth has well commenced, and before the shoots are so long as to be liable to be damaged in the process. Sprinkle the house two or three times a day in clear weather, avoiding a close moist atmosphere on the one hand and a dry one on the other. Dishudding should not be practised until the fruit shows in the points of the shoots.

Houses to Afford Grapes in May.—The Vines that are to afford Grapes in May must be started at once, nothing helping more than a bed of leaves and stable litter placed on the floor of the house and turned daily. The outside border should have the needful protection from cold rains and snow, two-thirds of leaves to one of stable litter, affording a less violent but more durable heat than dung. Provided the outside border were covered with bracken, straw, or litter in early autumn, so as to throw off the wet, the temperature will be considerably warmer than that of the borders exposed, and in their case covering with hot litter may be dispensed with. The inside borders should be brought into a thoroughly moist state by applying water, and in the case of Vines that are at all weakly give liquid manure at 90°. Start with a night temperature of 50° in severe weather, 55° in mild weather, and 65° by day, except the weather be very severe, when 55° will suffice, not exceeding those figures until the growth commences. Maintain a moist atmosphere by syringing occasionally, but excessive moisture excites the emission of aerial roots from the rods. Depress the rods of young Vines to the horizontal line or below it to insure the regular breaking of the buds.

Midseason Houses.—The Vines from which the Grapes have been cut should be pruned; indeed it is decidedly advantageous to prune the Vines directly the leaves have fallen, any Grapes still hanging having been cut and placed in bottles of clear rain water with a piece of charcoal in each. The Grapes will often keep better than on the Vines, as the temperature in the room is more equable than commanded in a vinery. Keeping Grapes hanging after the leaves have fallen may not be prejudicial to Vines unless prolonged to a late period, yet the greater extent of young wood keeps the sap more or less in circulation, and there is a certain amount of waste going on which cannot take place when the Vines are pruned. Prune, therefore, directly the leaves are down, and bottle any Grapes remaining, thin skinned varieties not requiring the maturing so necessary for Gros Colman and thick-skinned varieties generally. In pruning adhere to the system that has proved satisfactory. If the Vines are in good condition they will in all probability give sufficiently large bunches if pruned to one at most two eyes, good useful Grapes for everyday use, so essential when the table must be supplied with fresh fruit. But if large bunches are wanted, or the Vines from weakness do not afford bunches so large as desired, leave more growth, only be careful to select sound, round, well developed buds on firm ripened wood; aim, in fact, at finish. Large bunches are invariably defective of the finish of medium size bunches. Vines that afford well finished examples pruned to one bud will give a larger bunch and of equal finish from the second bud. If the soil be rich, loose, and plentiful, the chances are the shoots or canes will be gross, long-jointed, having large thin-textured leaves; the buds large, pointed, or if laterals are encouraged flat, and these may give the sensational bunches which justly have their merits calculated by weight. If on the other hand the roots are in a firm but favourable rooting medium, causing an increase of ramification, then the wood will be stout and short-jointed, the leaves thick and leathery, and the buds at their base will be round, plump, and well matured. It is, of course, assumed the foliage has full exposure to light for the solidification of the growth as made, and that cultural requirements are granted in full measure. Let the Vines be dressed, the house thoroughly cleansed and everything put into order, so that there need be no hurry to put things straight. Keep the house as cool as possible so as to insure complete rest.

Late Houses.—Every precaution should be taken against damp.

The most prolific cause of Grapes not hanging well is drip, it being useless striving to keep Grapes beneath a leaky roof, as a single drop of water getting inside a bunch of Grapes is sufficient to spoil it, though the decay may be only a berry, which, being in the interior, is not detected until the disaster is so spread as to spoil the bunch. Remove all leaves as they become ripe, affording only sufficient fire heat to exclude frost, keeping at 40° to 45°, and close the house in damp weather, and seeking to insure a dry, cool, and equable temperature.

Strawberries in Pots.—The plants introduced to the vinery, Peach, or other forcing house, should have the drainage scrutinised, making sure that it is free, and the loose surface soil removed, and a top-dressing given of dried cowdung or horse-droppings rubbed fine with the hands or through a sieve, adding about a twelfth part of steamed bone-meal, or some other approved fertiliser, well incorporated, then watering it with a rose-watering pot, so as to bring it into a moist state, for if placed on dry it washes off in watering the plants. The pots may then be placed in position after removing any decayed leaves, making sure that there is no deficiency of water at the roots, for the old leaves will not show signs of a deficiency of water until the soil is very much too dry for healthy root action, therefore rap the pots; a practised hand will readily detect by the sound which plants are needing water. Noble, La Grosse Sucrée, and Vieomtesse Hericart de Thury are good varieties for early forcing.

CUCUMBERS.—Winter plants must not be allowed to carry too much fruit. Unless they are extra strong remove two-thirds at least, removing also the male blossoms and tendrils with any superfluous shoots and bad leaves, but do not stop the growing points overmuch for the next few weeks, affording water moderately—a supply twice a week will suffice. Cucumber plants growing in pots or boxes will require water oftener, with liquid manure occasionally. A night temperature of 65° to 70°, falling to 60° in severe weather, 70° to 75° by day, advancing to 80° or 85° with sun, will be suitable. The plants will require moderate earthing at the roots from time to time, taking care that the soil has been previously warmed, press it firmly, but not hard. The bottom heat should be kept steady at about 80°. Atmospheric moisture will require to be moderate, damping only on bright mornings or early in the afternoon. If a night covering be afforded of mats or frigidomo to the glass it will be highly advantageous, but it must not remain on by day to the exclusion of light, every possible ray of which the plants must have. Remove old foliage and exhausted growths from the autumn fruiters, but do not overstop the growing points, avoiding overcrowding and especially overcropping. Fertilise the flowers during a continuance of dull sunless weather.

PLANT HOUSES.

Stephanotis floribunda.—Plants that have been pruned, cleaned, and had a complete season of rest may now be started into growth. A soaking of tepid water should be given, and the temperature raised to 60°. During the early part of the day syringe lightly, unless plants are beneath that would be injured by water falling upon them. In this ease the moisture of the atmosphere must suffice. If there is any mealy bug on the plants syringe thoroughly with petroleum and water of the strength advised a few weeks ago. It is much easier to destroy bug now than after the plants commence growth. Plants in pots that are full of roots should have a top-dressing of decayed manure. Those at rest must be kept moderately dry at their roots, and will be perfectly safe in a temperature of 50°.

Medinilla magnifica.—Where the wood has been thoroughly ripened by exposure to full sunshine during August and September the plants may be removed to the same temperature as advised for Stephanotis at rest. To flower them well it is necessary they have complete rest. Thrips is the greatest enemy this plant has to contend against, and should be destroyed by syringing the plant over a tank at intervals of a fortnight with a solution of tobacco water.

Gardenias.—These plants need watering with care, and strong stimulants in their present stage of growth must not be used, as more harm than good will result. If the flower buds have formed and commenced swelling maintain a temperature of 65°. If starved, overfed, syringed with strong stimulants, or checked in any way the flower buds are likely to be deformed. Plants that are not yet showing their flower buds will be safe in a temperature 5° lower. Tepid water may be used for supplying to the roots and for syringing.

Dracenas.—The atmosphere of the structure in which these are grown must not be kept too moist, or the points of the leaves that are highly coloured are very likely to damp. The temperature at night should range from 60° to 65°, according to the weather. Less water will be needed at their roots. Plants that have been used for decoration in rooms and other positions, and have been damaged so that they are useless except for stock, should be kept perfectly dry to harden and ripen the root portion of their stems. When cut up green and soft they are liable to decay early in the season. If kept dry for a month they will be ready for cutting up and starting into growth in brisk heat early in the year. Plants that have been grown purposely for yielding stock may be gradually dried to harden them.

Justicia flaricoma.—Where these plants have not been pushed forward place some of them in a temperature of 60°. They will be found very useful after many of the autumn flowering plants are over. The remainder of the stock will do for the present in any light structure 5° lower.

Begonia manicata.—If grown in a cool house the flower stems are only just showing, but will push up rapidly in a temperature of 60°.

They will be useful for the conservatory by the time they are in flower, but should be gradually hardened for removal to that structure just before the flowers are fully expanded. If removed direct to the lower temperature the flowers are very liable to fall. The remainder of the stock, and also those of *B. hydrocotylifolia*, which will be more useful in two months' time, may still be kept in a temperature of 50°. They must be kept rather dry at their roots, the atmosphere being in the same condition, and what watering is needed should be done early in the day, being careful to throw no more about than is absolutely necessary.

Nepenthes.—The points of any shoots that have been growing vigorously may be taken out or shortened back a leaf or two as the case may be. If done now they will soon start again, and they will again form pitchers freely. It is a mistake to allow these plants to extend above four or five leaves before they are pinched. Those which have been allowed to extend upright several feet in length should not be cut down for another six weeks, when cuttings can be inserted with some certainty of rooting them. Brown scale will infest these plants, and must be removed with the sponge. Thrips are sometimes troublesome at this season. The best means of destroying them is to syringe the plants over a tank with a weak solution of tobacco water. Less water will be needed at the roots, but be careful the soil is not allowed to become dry. Syringe on favourable occasions.

Cleaning Plants.—Every attempt should be made to clear plants from insects at this season of the year. They bear stronger insecticides now than during the growing period, and if every opportunity is devoted to this important work endless labour during the busy season of the year will be saved. Plants are often ruined or disfigured when cleaning is too long postponed. Merely cleaning them and then leaving them until they are infested again is no method of eradicating insects. They should be thoroughly cleaned, and then examined and syringed, as the case may be, at intervals of a fortnight or three weeks until every trace has been destroyed. It is surprising what labour is saved in the end by the adoption of energetic measures for a few months in succession.

THE BEE-KEEPER

QUEEN REARING IN RELATION TO HYBERNATION AND WINTER DYSENTERY.

(Continued from page 476.)

HEDDON, as I have said, contends that all his queens are reared in a "natural" manner. How he can assert this, and yet keep moving his old stock hive about to get rid of the bees puzzles me, as the old stock hive is never moved when bees are existing in a state of Nature. I am sorry to say that it is the fashion in the States to make any statement that appears to floor an antagonist, and I am afraid that some of our bee friends are not always quite proof against its influence, notwithstanding their good intentions, which I admit.

Dampness, bad ventilation, bad food, and cold have all been described as prime causes of winter dysentery; but wherever it has broken out I have been able in most cases, by learning how the queens were reared, to note that cheapness of production rather than high quality had been the ruling guide, Heddon placing the value of a queen as capital in a hive of bees as low as two cents., and Mr. W. L. Hutchinson, editor of the "Bee-keepers' Review," who teaches nearly all that Heddon advances, and is almost always a heavy loser from winter dysentery, says "one queen is as good as another in a hive if she has descended from the right stock." He contends that the manner of rearing has very little to do with it, though he seems to incline to the view that cells reared on the swarming impulse are the best to depend on for fine queens. Neither he nor anyone else who practises queen-rearing in America believes that after the cells are sealed it makes any difference where they are matured. The cells are nearly always cut out and hatched in the weakest nuclei, or they are hatched in "nurseries," which are of two kinds; one is heated by a lamp, and the other is a number of little boxes covered with wire cloth, in which a sealed queen cell is fixed. These boxes are fitted in a frame, and then hung in a hive of bees for the heat of the bees to hatch out. As the bees cannot get near the cells, the only heat they get is what is diffused in the hive, which I have proved is never equal to the temperature of the cluster on the brood (90°), but is often 10° to 20° below, to say nothing about the chilling the cells get while being cut out

and fixed in these cages. If we were to ask many of the people who rear their queens so to deny their cattle, chickens, or other young stock of all the warmth and shelter possible to give them they would laugh at us, and yet these do not require nearly so high a temperature for their full development as does an embryo bee.

In the natural course of things queens are reared in a hive; first, when the old queen is to be superseded; second, when preparing to swarm; and third, when the old queen dies or is killed. When the first takes place the stock is mostly very strong, and as they do not swarm the cells get thoroughly developed and matured, the first queen hatching killing the rest. If such a stock has not swarmed that season it does not do so until the next, and it proves to be a wonder in results. How often has it been noted that the best stock of a season was one that had not swarmed the year before? It was this one fact that led me to study the matter, and to think that the way the queens were reared had more to do with the matter than was suspected. Let us note the old stock hive after it has thrown three or more swarms, how often do the bees die of dysentery, or, it is remarked that it has "swarmed itself to death." Let us now consider what really takes place. We all know the shape of a queen cell, how it always stands out away from the comb, and hangs downwards even when reared on worker larvæ on the middle of a comb, and how the bees prefer to build them in passage ways, &c., where they can cluster round them. Has no one ever suspected that Nature designed that they should be reared in that way, so that the bees could cluster all round them to keep them warm and moist, as they require more heat for their development than either drones or workers? How, then, can they be cut out and developed in a lower temperature without weakening the constitution of the queen?

After the first swarm, if the weather sets in cold, and nearly always after the second swarm, many of the queen cells are practically left unprotected, the development of the queens in them is therefore retarded, a worthless queen being the result. The same takes place when a cell is hatched in a nucleus, nursery, or in a hive depleted of bees, as by the Heddon system. Therefore I have laid it down as an axiom, that nothing but a worthless queen will result from any cell cut out, no matter how hatched, on account of the variation of temperature while it is being cut out, nor can queen cells be lifted up out of a hive for examination without chilling them.

In this Journal for July 18th I explained how queens were to be reared, and I also showed that though queens were required in large numbers, they could be had in any quantity two days old without cutting out a cell or opening the stock hive to get them, and that by giving the old stock hive fresh eggs from time to time, a supply of queens can be had all through the season, which was the result of a discovery I made in 1887.

I will here make another definite assertion—viz., that if good queens are required, or queens whose bees will always hibernate, the first swarms must always be returned at once to the old stock hive, having first removed the old queen (which, with a few bees, will make up a nucleus, and if early, they will build up into a good stock for winter), to look after and develop the queen cells, whether increase of stocks are required or not. Such a stock will swarm again with a young queen, possibly a dozen, all of which can be used if required, if able to fly. If these queens are put at the head of good colonies, their bees, after the second generation, will surely hibernate, no matter what kind of food there may be in their combs, if it is their own storing. The form or degree of hibernation will be equal to that of wasps, which, like hedgehogs, always show signs of life if touched; nor will they, while hibernating, eat any food; so that they practically winter on nothing, but being in full vigour and vitality, they consume their stores in brood rearing in the spring.

In the United States very many people are specially engaged in rearing queens for sale, hence in that part of the world they are

most troubled with winter dysentery; and as their hives are very thin, long, and shallow, and ill protected against changes in the weather, the queen cells are often ruined should a cold night or two follow close on the issuing of a swarm. There are some, such as the Dadants, who use large hives and never have swarms, who are never troubled with dysentery, as the queens are only reared when the bees do so to supersede the old one, at which time stock is always very strong. It often happens that a spell of cold weather sets in soon after swarming commences; when this happens just imagine an eight-frame Langstroth hive, single walls, 18½ inches long, 12 wide, and 9½ inches deep, inside measure, and remember that the natural shape of the brood nest is a ball, when a good idea of what heat the queen cells get may be readily obtained. Such queens never safely winter, while other stocks swarming later get warm settled weather while the cells are maturing, which results in better queens. Heddon has been much puzzled to make out why in two apiaries, exactly alike in every respect, the bees should die in one and live in the other; he will now see the reason is they did not all swarm at once, as a cold night or two followed on swarming where the bees died. This could in many cases have been rectified had the old queen been kept, but the practice is largely followed of replacing all old queens with young ones.—A HALLAMSHIRE BEE-KEEPER.

(To be continued.)

WINTER DYSENTERY.

THIS subject, referred to by "Hallamshire Bee-keeper" at page 476, opens up a new field of discovery, which is to be hoped will be the means of banishing from our apiaries the winter scourge. One thing certain, a great many queens that have been reared artificially have proved failures, but whether that was from defective digestion or not I cannot say. There are few bee-keepers who have experienced three and four years in succession when bees had to be fed constantly, at the end of which they died from no apparent cause whatever but that of being reared so long artificially and on artificial food. Loquacious, but inexperienced writers on bee matters, pooh-poohed the remarks, but could offer no other solution than the one stated by—A LANARKSHIRE BEE-KEEPER.

•• All correspondence should be directed either to "THE EDITOR" or to "THE PUBLISHER." Letters addressed to Dr. Hogg or members of the staff often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post, and we do not undertake to return rejected communications.

Phalaenopsis amabilis (*C. L., Bristol*).—Your plant "with a panicle 4 feet 7 inches long and twenty-nine flowers" is a good one, but we have seen many others with more flowers.

Chrysanthemums and Primulas (*W. G. F.*).—You do not say for what purpose the Chrysanthemum blooms were sent. If for naming we cannot deal with them in an imperfect condition. The Primula blooms arrived buried in dry wool, hence spoiled. We have had no inquiries of the nature you suggest, and do not admire the last sentence in your letter.

Ornamental Grass (*E. O.*).—*Stipa elegantissima* is a perennial, and will grow again next year if the plants raised from seed have not been crowded too closely together, in which case they not unfrequently decay. Unless the plants have space to develop in the summer they cannot be expected to survive the winter; indeed, the autumn rains often destroy them.

Dressing Chrysanthemums (*T. Gover*).—If by a "professional" dresser, you mean a man has been sent for and paid to dress the blooms for winning a prize in a local class, we cannot express our approval of the practice, because the winner of a prize so obtained may be rewarded for work that is not wholly his own, and other competitors who represent their own skill only are placed at a disadvantage. We shall be glad, however, to hear what others have to say on this subject. The prize to which you allude cannot be withheld under the schedule.

Plum Trees Cankered (*A. B. C.*).—Your trees have probably been weakened by the heavy crops they have borne, and the consequent deprivation from the soil of the constituents that are requisite for healthy growth. You say nothing about the soil. It probably needs lime, and a bushel to the rod of about 30 square yards would not be a too heavy dressing, and a supplementary application of superphosphate of lime and kainit, or bonemeal and nitrate of potash, half and half, at the rate of 5 cwt. per acre, or 2 ozs. to the square yard, would very likely do good. If the soil is of a dry nature, 2½ cwt. of salt per acre may be applied, but this is not advised for cold, wet land.

Baronne de Prailly and Comtesse de Beauregarde Chrysanthemums (*S. B.*).—The publication of your letter could not lead to any alteration in the case mentioned, and in respect to the future the varieties are admitted as distinct in the National Chrysanthemum Society's catalogue, and when both are exhibited, undoubtedly true to name, in the same stand, the stand ought not to be placed "out of the running." We have repeatedly seen them included in an exhibit, and no thought of disqualification arose in the minds of the judges. There is the possibility of a person receiving, growing, and staging what he believes to be either one or the other of these varieties, and of its not being named correctly; in such case, though honestly exhibited, disqualification would be justified, yet the exhibitor might feel himself "badly treated."

Materials for Mushroom Beds (*W. H.*).—Nothing equals manure collected from stables in which the horses are fed on dry food and have little medicine. It may be collected at weekly intervals, shaken out, mixed and fermented as described in the work to which you allude. Peat moss litter is not suitable for beds in the open air. The ventilators may be closed when the trial sticks cease to be hot, yet while they are distinctly warm. We cannot at present recommend a man. When you secure one who is competent he will inform you when he needs assistance. It would not be profitable to grow Mushrooms for ketchup during the hot summer months. A paper containing the article you wish shall be sent to you in the course of a week. The prices mentioned for Mushrooms are more than sustained.

Greasing Fruit Trees (*Plum*).—We do not approve of applying tar and grease, or anything of the same nature, directly to the stems of fruit trees for securing the insects that crawl up them for depositing eggs; but much prefer securing bands of sacking, paper, or anything suitable, and well smearing these with cart grease and oil, Stockholm tar and oil, or resin and oil, two-thirds of the former and one-third of the latter heated and mixed. The subject was referred to on page 459 last week, and you will find an article in the present issue. November is usually named as the right time for applying the bands; but it is questionable if some of the moths do not emerge long before then, and it is certain that November applications have failed in preventing the blossoms and leaves of fruit trees being devoured by caterpillars. Mr. Wright, in his prize essay on Fruit Culture, says the bands should be applied in September, and it is better to be a little too soon than too late, but the bands must always be "sticky" for holding the insects. You had better procure the work in question, which can be had for a shilling through booksellers, or by post for 1s. 3d. from this office.

Carnations in Pots Failing (*G. H.*).—The first essential for success is healthy cuttings, sturdy and strong. With weakly cuttings or growths from unhealthy plants it is almost impossible to produce satisfactory results. The next point is to allow no check to the plants in their early stages of growth, and especially must care be taken that they are not permitted to be rootbound in small pots before they are shifted into larger. The want of timely potting results in many failures. The plants ought to be shifted, always before the roots are matted, into 8 or 9-inch pots, or even larger, and be grown in frames during the early part of the season, and afterwards in the open air, great care being exercised in watering them. If the plants must be grown in small pots liquid manure is essential after the pots are filled with roots. But whatever system of culture is adopted good plants cannot be produced from bad cuttings.

Gardening for Profit (*A Young Horticulturist*).—You should have sent your name and address. It is undoubtedly true, as indicated in the pamphlet on "Allotments," that many workers in gardens have risen from a very humble to a commanding position through the exercise of good judgment and great industry. Men with the smallest of means have become men of wealth. It does not follow that all who have started in commercial gardening have succeeded in their object, for many have failed—some from one cause, some from another. No doubt men assist masters to make fortunes, and some of these men might possibly do better by "working for themselves," as you say, but others would not. However, all are free to act in the manner they think the most conducive to their own interests. You say you "would prefer to be your own master." This you can be, but it depends entirely on

yourself and surrounding circumstances whether you would be more successful than as an earner of wages. All soldiers cannot become generals, but the more they strive and the fewer mistakes they make the better position they attain in the army of competitors. It is the same in gardening and other vocations of life.

Pruning Vines (F. J.).—So long as satisfactory crops are produced from spur-pruned rods we do not perceive the advantage of running up young canes between them, and then in the autumn not knowing what to do with them. It is prudent to provide young canes when the old rods show signs of failure, otherwise the practice is apt to cause overcrowding of the foliage in summer, especially when the main rods are only 3 feet asunder. However, assuming the Grapes are not quite satisfactory we should saw off all the spurs close to the rods and about halfway up them, paring the rough surfaces smooth with a sharp knife; train the new canes up the old rods and shorten them at about 6 feet, or so far as the old spurs are removed; then next year the crop along the lower part of the roof would be from the young canes, that above from the spurred rods. The young canes can extend to the top of the house during the summer, training them where the foliage can receive the most light; then if they are satisfactory in the autumn the old rods can be cut out, and the roof will be covered with young bearing rods, the lower half two years the upper one year old. But in carrying out this plan judgment must be exercised. Some of the old rods may be much better than others, and the young canes vary in the same way, and it would be foolish to remove spurs in the manner suggested if the young canes provided were not in a condition to bear better Grapes than the old parts removed. We can only indicate the method we have found successful, and leave you to exercise your intelligence and discrimination in carrying it out. If it succeed, you may take all the credit; if not, we shall not be disposed to take the blame.

Mildew on Roses in Pots (S. S.).—We have seen the Roses grown under glass by Mr. Bardney, and none could be cleaner, healthier, or more floriferous. His practice is to syringe the plants every time syringing is needed with the softsoap solution. It is important that the plants are clean to start with, and all trace of mildew has been removed, as well as aphides. If used from the time the plants are started regularly and thoroughly each time syringing is needed the plants will remain free from mildew, red spider, and to a large extent from aphides. It is difficult to thoroughly syringe all the points of the shoots, and aphides will appear, which should be destroyed at once by slight fumigations. Mr. Bardney, in addition to the softsoap solution, is careful in ventilating the structure in which Roses are grown. Cold draughts on the young tender foliage are certain to produce mildew. If these are strictly avoided and the plants watered with care, neither giving too much nor too little, you need not fear mildew if you persist in the use of the softsoap solution. For a dozen years Mr. Bardney has had charge of a house of Tea Roses, and never had to resort to placing sulphur on the pipes. From the time he starts his Roses he is careful never to admit air until genial weather in spring. The precaution is also taken to stop the ventilators, so that cold air cannot make its way through to the plants. The solution of softsoap advised is recommended as a preventive of mildew, and by its aid with careful treatment the plants can be kept free from its destructive ravages.

Excrescences on Peach Tree Roots (W. H.).—The roots of Peach trees in light soils are peculiarly liable to form excrescences of the description yours present, and very often with a strong tendency to throw up suckers. There is not any disease that we can detect, certainly no fungus, and we can only attribute the excrescences to a deficiency of calcareous matter in the soil. The roots in most cases of this kind are liable to penetrate deeply, probably in quest of moisture, which is inadequately furnished by the hot, loose, and dry surface soil, and we find nothing equal to lifting trees in such soil in an unsatisfactory state and laying the roots nearer the surface, an addition being made to the soil of clay loam, or preferably clay marl, to the extent of a fourth to a sixth, according to the lightness of the soil, the clay marl being broken up into as fine parts as practicable and incorporated well with the soil. We also find that by taking out the soil of the border to a depth of 2 feet 6 inches and placing at the bottom not less than 6 inches thickness of old mortar rubbish freed of laths, &c., that the roots do not pass through it into the gravelly or other unfavourable subsoil, the lime rubbish being a source of that element, and at the same time a reservoir of moisture through the absorbent nature of the material. The old soil can be used again, rejecting, however, any gravelly portions or sand, and replacing with strong loam in addition to the clay marl already mentioned. The soil should be made firm, but not formed into puddle by working in a wet time, and with surface mulching of rather lumpy manure, judicious watering or feeding with liquid manure, as necessity dictates, better results may be expected.

Treatment of Vines in Pots (Hopeful).—It is a very common practice to raise Vines from eyes one year, fruit them the next, and then throw them away. The eyes that were inserted last February and grown on, producing canes 8 feet 6 inches long, and now in 7-inch pots, may be suitable for forcing, and as they are "covered with plump eyes their whole length and appear to be well ripened," they may be given a trial. They will succeed well if potted in the compost you name, the pots being well drained and the soil made firm, the sides of which may be loosened a little, but care must be taken not to injure the roots, and there must not be any attempt at uncoiling the roots, potting with the ball entire. It would have been better had the Vines been established

in the largest pots, being shifted from the small pots in which the eyes were struck into the 7-inch, and from these early in June, or when the 7-inch pots are fairly filled with roots, into the 12-inch pots, in which they should be fruited. You may employ native guano as a surface dressing mixed with soil, being careful not to use it too largely, and all waterings may be of liquid manure in a tepid—i.e., of the same temperature as that in which the Vines are growing. The concentrated manure is also a good fertiliser, and may be used advantageously, the danger being in applying the manures, whether solid or liquid, in too powerful doses. The Vines should be shortened to a length of about 6 feet, and the cuts dressed with styptic or patent knotting to prevent bleeding. If there are any cuts made by removing the laterals they must also be dressed. The best varieties for pot culture are Black Hamburgh, Royal Ascot, and Madresfield Court of black Grapes; and of white, White Frontignan, Buckland Sweetwater, and Foster's Seedling. For later work, those named being suitable for early forcing, all the varieties can be successfully fruited in pots.

Storing Ice (R. T.).—As you have not an ice house you may preserve ice in stacks. A correspondent has described the following method, which he has carried out successfully for a number of years. "After getting the ice in proper working order, and the weather continuing frosty, we begin to take it off the pond and cart it home to the stack, which is built on level ground, but has the advantage of being shaded by trees and bushes from the strong sunshine. We begin the stack by emptying the carts on its foundation; after which there are plenty of hands ready to begin pounding the ice with light woollen mallets sufficiently small to pack all large pieces firmly, thereby excluding from the interior of the stack as much air as possible. This should rather be a little over than under done. The people on the stack pound away till the whole is finished, and as the ice draws towards a point one or two drop off as the room for working becomes less, and begin breaking the ice at the bottom before throwing it up to those who remain. As the work proceeds we now and then throw a quantity of water over all, so as quickly to congeal the whole into a solid mass. We stack in this way from 100 to 110 cartloads every year, and it keeps perfectly well over twelve months, sometimes for a longer period, and we have to open the stack nearly every day during summer. Before covering-up, if the weather will allow us, we leave the stack exposed at least twenty-four hours to the frost; if otherwise we cover it at once. For covering we use dry wheat straw, covering to the depth of 48 inches at least, and all put on at once. We leave no air pipe through it, and we have no trouble in consequence of its heating or fermenting. We leave the whole in a conical shape, neatly strapped down to keep off the rain. This may be thought a waste of straw by some, but no less thickness of thatching will enable us to attain our object. The straw, however, will not be altogether lost, as a farmer will know well what to do with it after it has done duty on the stack, when he has his cattle in the fold. We have no faith in having only twenty or thirty cartloads in a heap, however well protected and stored. There should not be less quantity than a hundred loads for a stack if ice is required all the year round." If the ice is stored in a dry or freezing state snow may be mixed with it, but if stored during a thaw snow is a disadvantage. Snow alone cannot be satisfactorily preserved for any lengthened period.

Sheds for Mushrooms—Saving Manure (A. O.).—Undoubtedly sheds are advantageous in sheltering from excessive wet; but in "open sheds" the beds would have to be of the same thickness as those outside, and he similarly covered with litter for the retention of the heat that is requisite for the growth of the mycelium and the production of Mushrooms between October and March. It is doubtful if the erection of open, or even closed, cold sheds, would be a profitable investment, having in view the "saving of manure." Even if the sheds were supposed to justify the making of somewhat smaller beds than is advised in "Mushrooms for the Million," the manure thereby saved would not equal in value the outlay incurred in saving it. There must be sufficient of material for fermentation, and the heat thus generated must be retained for insuring regular crops of Mushrooms. Occasionally, indeed often, the heat is sufficient, and retained just long enough for the spawn to run freely in the autumn, but Mushrooms do not appear till spring. That is because the heat is allowed to escape on the approach of cold weather. It would be practically the same if the beds were not thickly covered in cold sheds. In structures in which a temperature of 55° to 60° is maintained, little covering is needed, and beds made of the best materials, from a foot to 18 inches deep, afford excellent crops. Such houses are indispensable in private gardens where Mushrooms have to be cut daily, and especially where vegetables for salad and cooking have to be blanched for daily use; but if that method of Mushroom culture were viewed commercially, the cost of the buildings, heating appliances, and fuel, would have to be debited against the value of the produce; and we suspect that nine out of ten inexperienced persons would lose far more than they would gain by adopting that method. Broadly speaking, it may be said that, if a person cannot grow Mushrooms profitably on the outdoor-ridge system, he cannot grow them profitably in any other way; but if he has fairly good results from that plan, he may expect somewhat better returns from a similar practice in sheds, though the beds must be large enough to generate heat there, and be covered for retaining it. The idea of running a flue under each ridge for imparting the requisite heat to the smallest possible bulk of material, is wholly fanciful; the heat must be the result of fermentation in which moisture is an essential, whereas artificial heat would dry the beds and render them quite unsuitable for their purpose. If you wish

to grow Mushrooms profitably, you had better follow the methods of persons who have had the greatest success in their culture, and they do not incur the expense of building sheds for saving manure, but spend the money the sheds would cost in the purchase of the requisite quantity of manure, and if they could not obtain this they could not grow Mushrooms. In the railway tunnel at Edinburgh flat beds have been tried, but abandoned in favour of the ridges. If you wish to discover new methods of producing Mushrooms, by all means make experiments, but be prepared to lose some money in the enterprise. If you desire to grow a few for your own use with the least quantity of manure, do like some others, press the best you can obtain in boxes a foot deep and place them in a cellar or room in which the temperature does not long remain below 50°. If you want to know anything more write again, and you may perhaps elicit information that will be useful to others as well as yourself.

Propagating Conifers (W. R.).—At no period of the year is the propagation both of hardy flowering shrubs and Conifers carried on in nurseries with greater rapidity than from the end of August onwards. The majority of Conifers are propagated by means of cuttings and grafting, many Pines excepted, and a few common varieties of Cupressus, which are readily raised from seed. The system adopted where the work is carried out on a large scale entails much labour. Narrow beds are formed about 2 feet wide, with a row of bricks placed edgewise on each side of the bed, leaving the tops of the bricks just above the soil. Handlights or small glazed boxes about the same width, and about 3 feet 6 inches in length, are in readiness before the cuttings are inserted. A heap of coarse river or red sand is placed at hand, and a good proportion is mixed in the soil, the surface being covered about half an inch in depth, after which it is ready for the cuttings. These, when the wood is fairly ripened, are frequently taken from the plants intended for sale, and others from stock plants kept in borders for the purpose. Some care is necessary in taking them so that the plants be not disfigured. The portions intended for cuttings should be so taken that when dressed each will have a heel. It is necessary that the cut be cleanly done with a sharp knife. The cuttings should be made clean for about an inch of the stem near the base, and should be from 2 to 4 inches in length, but the length matters little provided a good heel is left and the wood is in a proper state of ripeness. This mode of making the cuttings applies with equal force to all the Cupressus, Thuia, Retinosporas, and many others, but such kinds as Cryptomeria elegans, Retinospora ericoides, and others equally free strike readily without a heel. The cuttings are inserted as thickly as possible under the handlights on the prepared border, making the soil firm around them. A good watering is then given and the handlights placed over them. These miniature frames are generally arranged in rows, leaving about 2 inches between each bed to allow room for the frames to be removed as occasion may require. Little trouble is necessary afterwards, only giving shade if the sun proves very hot for a time after the cuttings are inserted. It is scarcely necessary to again lift the lights before the early spring, as the cuttings seldom need water before then. Sufficient will soak in round the handlights during wet weather, and keep the soil moist during the winter. The cuttings should be kept as close as possible until they are well callused, which will be the case in spring, as if air is given in their early stages many of the cuttings may damp off. During winter the only attention that is needed is to cover the frames with mats or other protecting material in severe weather. It is better if they can be so covered as to exclude all frost, but this is not absolutely necessary. I have seen the soil frozen hard for a long time and little or no injury has resulted therefrom. Another course of propagation can be effected by placing the cuttings in pots in the Conifer house, which is generally kept at a temperature of 40° to 45° during the winter. This system is practised to a large extent because smaller cuttings can be employed, which is often convenient with new and choice varieties.

COVENT GARDEN MARKET.—DECEMBER 4TH.

OUR Market is now very quiet, home-grown produce coming very light. Apples chiefly supplied from Nova Scotia and Canada, samples ruling inferior. Grapes in good supply with prices low.

FRUIT.

PORK AND BACON.

Now is the time when we begin pig killing for home consumption, and the addition of choice home-fed pork to the household dietary is a welcome one, both as sausages and in joints; but pickled pork does not hold the prominent place at table that it used to do, yet it is undoubtedly both wholesome and palatable. Time was in our recollection when two or three huge tubs of pickled pork were always part of our winter supply from the home farm, but taste changes, and pickling tubs for such a purpose are very much a thing of the past.

Well cured bacon and hams are and always will be in constant request, and the home farmer has now to gradually make an ample provision of both for the next twelve months. In view of this care was taken as the store pigs were withdrawn from the stubbles after harvest to select enough of them with large long bodies to fatten gradually for this particular purpose, the more forward ones being pushed on quickly, to be followed by others as fast as the curing can be done, the number to be cured at a time being entirely a matter of convenience, and the total number according to the supply required. The farm produce book should always enable one to see at a glance the probable number of hams, sides of bacon, and chaps that will be wanted; but we always take good care to have a safe surplus for emergencies, such as extra company or a change of cooks, the latter especially often making a material difference in the quantity used, some chefs being very big men indeed, whom it is unwise to offend, as they have it in their power to make matters very unpleasant at the home farm, so that provided they keep within reasonable bounds it always answers best to meet their requirements with promptitude and cheerfulness.

Hams of about 20 lbs. weight are a favourite size, and we have pickling pans large enough to contain two of these on end side by side—not laid upon each other—in the pickle, where they are turned daily for a month. The pickle for each pair of hams con-

sists of 2 lbs. of salt, 3 ozs. saltpetre, 3 ozs. bay salt, 3 ozs. shallots (bruised), 1 oz. coriander seed, 1 oz. juniper berries, 4 lbs. treacle, $\frac{1}{2}$ lb. beef suet, with enough water to quite cover the hams. The ingredients are well stirred into the water, and when the daily turning is done the hams are rubbed with those parts of the pickle which do not dissolve. We are particular about details here, as we have often found beginners very stupid as to the precise manner in which the pickling is to be done, and have repeatedly found the mixture used without water, the hams being rubbed with it daily; but as there was no liquid pickle the curing was imperfect and the result unsatisfactory.

At the end of the month the hams are taken out of the pickle, put into separate bags (either of paper, or preferably of thin sack-ing), and suspended in the smoking room or chimney for about another month. Some prefer to smoke them longer, but a month is sufficient for all practical purposes. They are then taken out of the bags and suspended from hooks in the store or bacon room, and are ready for use then or any time for the next twelve months. The flavour of hams so cured is peculiar and delicious, being liked by the most refined palates, all that is wanted to crown our work with success being the final operation of cooking. It might be thought that to cook a ham is a very simple matter; so it is with ordinary care, but we have known many a well-cured ham spoilt in the cooking, simply because it was left to an ignorant kitchen girl. In one instance the ham was sent to table half raw, the glib-tongued excuse being that it was badly pickled; in another it was so much overdone that the fat was quite white, and it was only when we had another ham of the same batch brought from the farm and cooked in our own kitchen that we could convince the careless cook's master that his highly paid servant was to blame.

Our bacon is cured in sides off which the hams only have been taken. The pickle is made with salt in the same proportion as for hams, with the addition of 4 ozs. each of saltpetre and soda to each 40 lbs. of pork; the saltpetre imparts colour, and the soda prevents the lean part from becoming hard. For very mild-cured bacon there must be less salt used, but we do not think it wise to attempt this at the home farm where bacon has often to be kept so long. Bacon of excellent quality can easily be had by keeping it covered with the pickle and smoking it as was explained for hams. In the large chimneys of an old farm house the smoking can be done perfectly, provided non-resinous wood only is used, such as Oak or Beech logs, but without such chimneys there must be a separate building for the smoking.

WORK ON THE HOME FARM.

A test of good management of poultry is a regular supply of eggs now, which is only to be had where enough pullets were saved from March, April, and May broods. Of a considerable number of poultry which have lately come into our hands only one hen lays, and anything like profit is out of the question till next spring. Now this ought not to be, yet in a matter so simple and so clear it is quite exceptional to meet with a full supply of eggs in winter. We call attention to the fault once more, in order that unwilling or unintentional defaulters may resolve to set matters right next season. Another fault which we must set right are the badly arranged perches of one of our fowl houses. The fowls can get up well enough at night, but in the morning many of them cannot fly down without knocking themselves about. We proved long ago that very low perches afford no real remedy for this. If it is possible to reach a high perch of any sort up they will go, as Nature prompts them, and the only plan is so to arrange the perches that all the fowls can come down easily from them. With legs of mutton at 10 $\frac{1}{2}$ d. per lb., poultry of all kinds should have a brisk and profitable sale. Turkeys are now fast being finished for Christmas markets, and as they are sold by weight high feeding answers better with them than for other poultry sold by the carcass. Some of the best young ones will be selected for stock birds for next season, as it hardly ever answers to keep over old birds. A well fattened gobbler weighing from 20 to 25 lbs. makes a noble appearance for the supper table of a Christmas party, but a regular weekly supply, plump if small hens, are liked best.

Where there have been losses from gapes and a totally new run cannot be had, the surface should either be turned over or fresh earth, ashes, or gravel laid down during winter sufficiently thick to prevent further risk of contagion. A badly built fowl house is being made warm and snug by having the interior lined with match-boarding. This is a somewhat expensive but thorough remedy, which is the best thing to do under the circumstances. We have seen an excellent and

very durable poultry house with sides and roof entirely covered with corrugated iron sheets fastened to a wooden frame.

OUR LETTER BOX.

Agricultural Chemistry (W. G.).—There is an excellent series of papers on agricultural chemistry in "Cassell's Popular Educator," which work we highly commend to all young men striving to improve their education. Of books get "Chemistry of the Farm," by R. Warington; "Life on the Farm—Plant Life," by Maxwell T. Masters, published at 2s. 6d. each by Bradbury, Agnew & Co.; "Science Primer—Chemistry," by Professor Sir H. Roscoe, 1s., published by Macmillan; "Lectures at King's College," by F. J. Lloyd; or "Agriculture," 12s., published by Longmans; "Agricultural Chemistry and Geology," 6s. 6d., by Professor Johnston, published by Blackwood; "First Year of Scientific Knowledge," by M. Paul Bert, 2s. 6d., published by Relfe Brothers, Charterhouse. You will also find useful "Students' Chemistry," by A. J. Bernays, published by W. H. Allen & Co., 13, Waterloo Place, Pall Mall. We cannot give you the price of this, as ours was a presentation copy. The third part of Stephens' "Book of the Farm," 10s. 6d., contains much valuable information on the subject, and when you become familiar with the rudiments you will find the English edition of Ville's "Artificial Manures," 21s., published by Longmans, will repay you for close study. Try also to see the periodical reports of the various associations for the promotion of scientific agriculture as they appear.

Maize—Improving Pasture (E. R., Lancashire).—The advice given you to dibble Maize in your pasture in view of obtaining "a heavy crop of something sweet and juicy," is simply absurd. It is true that Maize will yield a heavy crop—as much as 30 tons per acre of valuable green food either for use in summer or as chaffed silage for winter use—but it requires soil that is well tilled and highly manured, as well as from three to four months of warm genial weather for its development. It is so sensitive to frost that it is not sown till June in the southern counties, so that it is not fully in use till about the third week in September. This explanation will enable you to decide if your climate is suitable for it. Now for the soil. You say it is shallow with a subsoil of clay. Maize revels in a deep rich soil, but it answers well enough in a light soil heavily manured, and you might try a patch, but remember there must be no dibbling in pasture, but thorough cultivation with plenty of your stable manure, and any of the Maize sold in shops will answer. But why not try and enrich your poor pasture? A heavy dressing of old stable manure applied at once would much improve it for next season, and a regular annual dressing would ensure sustained fertility. If, however, the herbage of the pasture consists of poor indigenous grasses, then we should break up the pasture, work plenty of manure into the soil, and sow it as early next spring as the weather will allow, with mixed Grasses and Clovers for a four-years layer—a temporary pasture, in point of fact—with the mixture offered by any of the great specialists advertising in this paper. Such pasture would yield heavy crops of rich succulent herbage, altogether superior to that which you probably now have. But pray remember it must have a heavy annual surface dressing of manure after the first season, if of stable manure in the autumn, if of chemical manure early in spring. Should you decide to retain most of the permanent pasture intact you would find a few perches broken up and sown with Lucerne in rows wide enough apart for hoeing between would afford you a valuable successional supply of green food for your pony throughout summer.

ROOTS AND GRAIN AT BIRMINGHAM.—Messrs. Edward Webb and Sons, in directing our attention to their stand of roots and grain at the Birmingham Cattle Show, send us a list of prizes that have been awarded for their specialities, the very length of which precludes its publication. Twenty-nine first prizes at one show ought to satisfy the most enterprising.

REMARKS.

- 24th.—Occasional showers, but fine with a little sun for an hour or two at midday.
 25th.—Brilliant throughout.
 26th.—Bright morning; heavy shower with a little wet snow or sleet from 1.45 to 2 P.M., and bright again after.
 27th.—Fine, cold and frequently bright morning; slight snow showers whitening the ground in the afternoon.
 28th.—Bright and cold throughout.
 29th.—Fine, with sunshine at midday.
 30th.—Dull and slightly foggy till 1 P.M., then clear but cold.
 Sharp fall of temperature from the previous week, the present one being below the average.—G. J. SYMONS.

FERNS.

FERNS have much natural beauty to recommend them, for with a prevailing grace of form we have a surprising range of variation in frond outline, composition, and habit. Flowerless themselves, they constitute admirable foils to the rich colours and showy or delicate flowers of other plants. In this way they are invaluable for decorative purposes, but alone they possess sufficient beauty to command a place in gardens, and those who have taken up their culture as specialties have soon become as enthusiastic as orchidists and others who have made studies of particular plant families. Nor are the attractions of Ferns confined to exotic species, for the almost innumerable varieties of British Ferns present some charming frond developments, many in delicacy and intricacy of detail equalling or even surpassing the best introductions from other countries.

To form an idea of the marvellous extent of variation in Ferns it is only necessary to glance through the great collection at Kew, noting the stately tree-like *Cyatheas* and *Dicksonias*, which rear their imposing crowns of fronds far above all their relatives; the graceful *Adiantums*, the powdered Gold and Silver *Gymnogrammas*, the luxuriant and elegant *Davallias*, the exquisitely beautiful *Cheilanthes* and *Nothochlænas* with fronded tracery, the distinct climbing *Lygodiums* forming long wreaths and festoons of twining fronds, the bold *Aspleniums*, the rugged *Marattias* and *Angiopteris*, the creeping *Polypodiums*, and lastly those gems of the Fern world, the "Filmies," *Trichomanes*, *Hymenophyllums*, and *Todeas*, the translucent fronds of which appear in some cases frosted with crystals or glittering with liquid diamonds. There are only a few of the types that take the attention of a passing visitor to our national collection, but to those who possess a more intimate knowledge of the hundreds of species now cultivated in British gardens there are abundant other attractions of scarcely less importance; in fact nearly every individual Fern is invested with sufficient character to render it an interesting study to all who care to devote a little time to its careful examination.

Many amateurs have made specialties of some genera, or even of the varieties of certain prolific species, but this has chiefly been done with British Ferns and the "Filmies." Collections of the former are frequent, particularly in the north of England and around such towns as Sheffield. Wonderful collections have been formed by the late Mr. Carbonell and Mr. Lowe near Uske in Monmouthshire, by the late Colonel Jones near Bristol, and others; while of smaller collections there are hundreds of considerable interest, to some of which we shall have occasion to refer in the course of these notes.

The decision of the Royal Horticultural Society's Council to hold a Fern Exhibition and Conference in 1890 was a wise one, for there is no doubt that from a public exhibition point of view Ferns have been comparatively neglected. Their history, structure, and culture, too, afford abundant materials for discussion at a conference, which can easily be rendered of an exceedingly interesting and important character. It is true that some societies have provided classes for specimen Ferns at the larger exhibitions, the northern societies in particular also giving encouragement to hardy Ferns, but beyond that little has been done. Two important exceptions must, however, be noticed—namely, at Brighton and Bath, where attempts have been earnestly made to do justice to

this large and beautiful family of plants. At Brighton classes have been devoted to groups of Ferns arranged for effect, and the results have been satisfactory in the extreme, instructive as showing what can be accomplished with Ferns alone, and affording a refreshing contrast with the bright masses of colour furnished by *Pelargoniums* and other flowering plants. Compared with the conventional groups at shows these are far superior when tastefully designed, not crowded, but allowing every distinct character of frondage and habit to be distinctly seen. Much, of course, depends upon the individual taste of the competitor and the Ferns at command, but diversity of style often compensates for a restricted collection of varieties, the banking method being avoided in all cases. The Bath Society at one of their summer shows a year or two since had a large tent exclusively occupied with Ferns, British varieties largely predominating, and the late celebrated pteridologist, Col. Jones, was one of the chief exhibitors with others in the district, and Messrs. W. & J. Birkenhead from the north. In a large experience of shows throughout this country I have never seen a more interesting or pleasing tent of plants, and it was quite refreshing to turn from the gay floral display in other portions of the grounds to the coolness and varied shades of green in the Fern tent. These are only examples of what can be effected in exhibition of Ferns, and working upon some such lines as these the Royal Horticultural Society will have little difficulty in producing something quite worthy of their efforts.

With regard to the commercial value of Ferns for decorative purposes it might be safely stated that, though as collections representing the family, Ferns are neglected in private gardens, yet never in the history of horticulture have they been so extensively employed for house adornment and in floral arrangements as at the present time. It would be difficult to estimate the number of Ferns sent into the markets in the course of a year, and impossible to give even a vague idea of the quantity of cut fronds of *Adiantums* and other Ferns either sent from growers in this country or imported from the continent. Suffice it that some "market men" devote themselves almost exclusively to Ferns, and there are several large growers around the metropolis who derive a substantial income from the sale of these plants alone. Wherever cut flowers are a special feature in market nurseries Ferns are grown extensively as well, and a consignment of flowers for sale would be deemed incomplete without its accompanying proportion of Fern fronds. The extension of the cut flower business has induced a corresponding increase in the demand for suitable foliage, and the result has been that a great stimulus has been given to the culture of Ferns. Of course, few species are grown for this purpose, *Adiantum cuneatum* and its variety *gracillimum* largely predominating; but amongst the importations we have several others, and it might in some cases be worth the attention of market growers whether they could not add to their stock of varieties.

In the general nursery trade nearly every firm of any importance has a department for these plants, but few have made specialties of Ferns in the same way as Messrs. J. Veitch & Sons of Chelsea, Messrs. B. S. Williams & Son of Upper Holloway, and Messrs. W. & J. Birkenhead of Sale near Manchester. For many years these firms have steadily increased their collections, adding to them all the best of the novelties obtainable, either amongst new introductions or home-raised plants, and now together they comprise nearly all the Ferns in cultivation in this country.

As a collection, however, that in the Royal Gardens, Kew, is unrivalled, and as the history of its advance is to some extent the index of Fern progress in Great Britain, we may appropriately glance at the record thus afforded us.

The first edition of Aiton's "*Hortus Kewensis*" was published in 1789, and in it were included sixty-seven species of Ferns, a small proportion of which were exotics, chiefly from North America or the West Indies, comprising *Onoclea sensibilis*, *Osmunda regalis* and *cinnamomea*, *Pteris longifolia* and *arguta*; several

Aspleniums, *Dicksonia arborescens*, and *Adiantums reniforme*, *pedatum*, *villosum*, and *fragrans*. That fairly represents the number of Ferns in cultivation one hundred years ago, a remarkable contrast with the present knowledge of these plants. The second edition of the same work was published in 1813 and 1814, when the number had increased to 120, thirty-seven being natives of Great Britain. Whether all these were represented by living plants in the collection is doubtful; at any rate, Mr. J. Smith has told us that when he entered the Gardens at Kew in 1822 he found only forty tender exotic species in the various houses. Three years later the tropical Ferns were arranged together in one house, occupying a space of 6 feet by 12 feet, forming the commencement of the present large collection. Mr. Smith applied himself closely to the increasing of the numbers of cultivated Ferns during the next twenty years, with what success can be judged from the fact that he published a list in an appendix to the "Botanical Magazine" for 1846 including nearly 400 species. A catalogue issued ten years later—namely, in 1856—gives 504 species, and this number was still farther increased in 1868 to 802 Ferns and 48 Lycopods. In 1882 the total remained practically the same, as, while many new species had been added, others had been either excluded or lost. Since then there has been a great advance, for a list prepared during the present year, and which will shortly appear as a special issue of the "Kew Bulletin," the total number of Ferns is 1261, of Lycopods 108. This, too, does not include the varieties of *Scolopendrium*, *Asplenium Filix-fœmina*, *A. aculeatum*, *Nephrodium Filix-mas*, *Polypodium vulgare*, and other British species, the number of which has been so greatly increased by the collection bequeathed to Kew by the late Mr. Carbonell. About 4000 plants were thus obtained, comprising probably 2000 varieties. The Cooper Forster Filmy Ferns have also enriched the collection greatly, and, with some much-needed alterations in the structures devoted to the plants, and an excellent system of management, the condition of the plants has been wonderfully improved. It now constitutes one of the best departments in the whole establishment.—LEWIS CASTLE.

(To be continued.)

TOMATOES IN 1889.

TOMATOES have proved an abundant crop this year both indoors and outside in favoured positions on walls. They have not, however, been grown without considerable anxiety on the part of some cultivators, for disease in some gardens has been very troublesome. The remedial measures taken, although probably having a deterrent effect on its progress, were not effective. Nothing that I have heard of has yet proved fatal to its growth when once the plants are attacked. Plants growing outdoors do not appear to contract the disease as do those produced under warmer conditions under glass; but although cooler and more airy conditions are less favourable to the spread of disease, they are more liable to that which infests the Potato during the late summer and autumn months, when it becomes prevalent among these crops. Undoubtedly the spores are carried by the wind in all directions, as last autumn the first sign of this pest was observed on a Tomato plant growing directly under a ventilator of our Peach house, in which we grew the greater portion of the crop, and once established within it very soon wrought havoc among the remainder of the plants. So severe was the attack that in a very short space of time it became necessary to cut all fruits and clear out the plants. Fortunately, however, we had not been troubled with any this season indoors or out, but we have had our share of that more greatly dreaded *cladysporium* or Tomato disease. Its first appearance was noticed on a plant of Hackwood Park, obtained among others by a friend in Hampshire, who, strange to say, has not had a trace of it among his crops this year. Whether the disease is perpetuated in the seeds I have not had experience to prove, and I am not likely to run the risk in saving any from our own stock. In an adjoining house it made a much later appearance, although the side ventilators opened from one into the other, and there again the Hackwood Park variety was the first attacked. Directly it was observed every apparently affected leaf was promptly removed, and the remainder, together with the stems, were given a good

dressing of sulphur, but unfortunately it did not have the desired effect.

In growing a number of varieties there is much to interest one in comparing their respective merits, especially when planted in a continuous line, where they come within easy view. When grown for home use merely the fewer sorts in such cases the better. For high qualities, combined with free cropping, none that I have seen this year can excel the Orangefield. I saw a large houseful of a good selection of this variety in spring bearing a crop such as I have never seen equalled, and only one, or the most two other sorts, were grown for trial; but I imagine they will not find space another year in that garden, excellent varieties though they were for exhibition purposes.

With us, although numbers of sorts are grown, Reading Perfection still holds its own, and several more under other names bore very close resemblance to it. Our next in point of favour is Daniels' Crimson Queen, a beautifully shaped dark-coloured fruit, and bearing a heavy crop, both in pots and outdoors. Gilbert's Surpasse is a distinct medium-sized fruit and a free cropper. Mikado and Carters' Dedham Favourite are not appreciated on account of their colour—a cornelian red; but the newly selected form of Mikado is a splendid variety of a dark crimson colour, and very distinct. For winter and early spring cutting a good selection of Large Red and Suttons' Earliest of All are indispensable. Among the yellow or golden-skinned varieties Golden Eagle is a great favourite with those who use them as dessert, the flavour being exceptionally good, and is very productive. Large Yellow gives larger fruits, but are much paler in colour, and the flavour insipid compared with Golden Eagle.

Some good fruits have been gathered from open walls; the heaviest we have cut weighed 14 ozs. They may have been secured of larger size by thinning, but preference was given to quality rather than fewer sensational fruits, which are less useful. The last of our crop were gathered outdoors on October 18th. These were placed on shelves in the greenhouse to ripen gradually, and will continue the supply for some time hence. Altogether the year 1889 has been generally favourable for Tomatoes, and outdoors in particular, but it will be long ere it will be forgotten, and its association with diseases, which in some districts have followed them with such persistency. It is to be hoped that we shall not be favoured with a repetition another year; but such hopes, it is feared, will not be realised, as there is danger of spores being retained sufficient for further impregnation.—W. S., Frome.

LILY OF THE VALLEY.

ALTHOUGH forestalled to some extent in some notes on the above subject that I had in hand, by those of your correspondent Mr. Frampton (page 208), yet a few remarks on the comparative methods of culture may be of interest. In deference to an expressed desire to be favoured with blooms of this favourite plant during the early winter months and onwards, a special effort was made to obtain them, but as most of those who have attempted to force this plant into growth before the turn of the year will readily testify, this proceeding is not always such as results in much satisfaction. With us fortunately, in the establishment where I was at that time engaged, the financial point of view was not of primary importance, or the attempt would soon have been discarded as hopeless, for crowns of the finest quality were at our disposal, and so far as our knowledge of the proper treatment went, they received the best of attention, yet our labour brought but small returns. A few spikes rose here and there from the various supplies introduced into the forcing house (potted in a similar way as mentioned by Mr. Frampton) as soon as it was possible to obtain crowns, but not until the early spring months was the simultaneous starting into growth of a whole batch expected, and so regular had this become, that the number of crowns, technically known as "gibbers," placed on to the rubbish heap, would have astounded a regular market grower had he purchased a similar lot and obtained such small returns.

Since that time I have passed through establishments where the most had to be made of the means at disposal; and in this case, as in some others, I have observed results far superior to where cash supplements skill in the production of successful results; and it came as rather a reverse to find that we were expected to grow our Lily of the Valley outright, instead of purchasing it already half grown. But as the system has been in vogue apparently for some time, I watched the operation closely, and so convinced was I, that I have since paid more attention to the home-cultured roots than I had previously considered profitable. With imported roots we considered it fairly good to obtain 75 per cent. of spikes a fortnight before Christmas, whereas with improved treatment and

home-grown roots we have had spikes by the second week in November and from December onwards.

The stock from which we are now obtaining our crowns for present forcing was secured from a few square yards dug up some four years since in a corner of the kitchen garden, where it had, judging from the closely woven mass of roots and number of tightly packed crowns, been undisturbed for a number of years. All the best flowering buds were selected which, when introduced into heat during January, promptly produced strong spikes of bloom with fine healthy foliage, while imported roots under similar treatment were almost destitute of leaves. A second selection was reserved for planting with the object of producing crowns for the following year's work; these, placed on a south border in a rich soil in rows 6 inches apart, and some 2 inches clear of each other, made strong plump flowering buds by the autumn. The remainder of the heap of roots was distributed in an open quarter of the garden in a somewhat similar manner, plenty of good rich manure being worked in as planting proceeded. Strong growth was the result, and an almost incredible stock of good flower crowns for forcing has now rewarded our efforts.

The first were dug up towards the middle of October last year, and after removing all lateral crowns that of course do not contain a flower bud, they were spread out behind a north wall with the object of inducing a premature rest; in this we were assisted by a sharp touch of frost, which so far from injuring them is, I am inclined to think, decidedly beneficial when they are wanted for extra early forcing. Of course care was taken to prevent them suffering from drought, as I am of opinion that this is sometimes the cause of their not starting into growth so readily as they should, a opinion that is also shared by a market grower of my acquaintance, who speaks of the consignments of a firm of home growers in the eastern counties that pack their roots in casks for travelling as being always reliable in starting promptly.

Unlike Mr. Frampton we do not consider turfy loam, leaf mould, and sand a necessary medium for placing the roots in, seeing that the existing roots remain persistently dormant, and not a single fresh feeder is emitted while being forced, a curious state of affairs that has probably escaped Mr. Frampton's observation. Cocoa-nut fibre refuse is our favourite substance, and it appears to be specially adapted for this purpose; heat-retaining without fermentation, antiseptic and moisture-holding, it constitutes a most useful article for many purposes in the forcing house.

The cavity over a hot water tank that is used for propagating is filled with about 6 inches of this material, and the crowns distributed below over the bed, and about an inch below the surface. The whole receives a thorough drenching of tepid water, and the heat is turned on until the plunging thermometer registers at least 95° or 100°. Under the combined influence of this amount of heat and moisture, other things being equal, the spikes soon commence to push through, when the heat can be slightly reduced. Should pot plants be required the forwardest roots can be withdrawn and placed in a uniform manner in suitable sized clean pots, using some of the cocoa fibre by preference. For earliest supplies a few growth crowns should be included, which will prove useful in making up pot plants, or a root of Solomon's Seal (*Polygonatum multiflorum*) can be placed in some convenient corner of the forcing house to supply leaves of almost similar likeness to the plant's own, when such are desired to be used for cut purposes. The association of the plant's own foliage with its flowers should be managed if possible, as in my estimation much of the charm of the beautiful plant is lost when presented in its usual early forced condition.

Not having, as yet, had the opportunity of testing the merits of the Berlin variety when grown at home, I cannot say as to its adaptation for early forcing, but for that purpose throughout the spring months it has no equal, the variety under present cultivation being the common Dutch; though smaller in spike and individual flowers, it is for general purposes of spray and button-hole bouquet-making none the less useful.

We have at present the second roots in flower, from which I send a few spikes for your inspection. The first was not this year quite so successful as usual; this we attribute to the unusually mild autumn and absence of autumn frost that is now considered almost necessary to prepare the crowns for early forcing. I should be interested to know why Mr. Frampton prefers a substantial loam for their cultivation, as I generally find that the finest imported crowns appear as if they had been growing in a very sandy soil, and on this presumption we have always endeavoured to make the quarter in which we have planted as light as possible. Moreover, I am of opinion that a light soil conduces to early ripening of the crowns, and the plants themselves with us certainly flourish better in these quarters than in others when the

soil is naturally of a most exceptionally substantial character.—M. COOMBE.

[The flowers in question, which were accompanied with leaves, were referred to on page 487 last week.]

IMPROVING FRUIT TREES.

MIDWINTER is not the best season to attempt the improvement of wayward fruit trees, but it is better to take them in hand even then than to allow them to go on producing poor crops of deformed and "scabby" fruits. The younger the tree the less difficult is it to bring it into a fruitful condition, and although very old fruit trees may be rejuvenated, there is doubtless a stage when the time for this is past. In the case of very old trees—referring here to Apples and Pears—the best plan is to cut over the head, and allow only a sufficient number of branches to grow as will form a good tree either in the open or on a wall. If good strong growths are made for a couple of seasons the roots may then be taken in hand; though the mere removal of worn out branches and the production of young ones may and often does bring the tree into a fruitful condition, but this will not be lasting. Therefore it is as well to cause the trees to produce a new set of roots.

If an Apple, and the main roots are numerous, one-half may be cut at 3 to 4 feet from the stem, and working underneath so as to cut all down-going roots. If the subsoil is bad it must be removed and good supplied, but where the soil is in fairly good condition it may be broken up and returned. Comparatively few gardeners have it in their power to add turf or loam, and where they can do so the time may be wanting. It is, therefore, well to know that good results follow from merely turning over the soil as above. If the roots are found to be few and large it may be safe to be content with the cutting to 3 feet from the stem of one such root, leaving the cutting of more till another season.

In the case of large Pear trees, especially those trained against walls, it is advisable to proceed with great caution; and it will be found better to cut 3 yards or so from the stem, and not going more than halfway round the one season. If these cut roots produce a good number of root-breaks the season following, and the foliage made be strong and healthy, then the succeeding year undertake the pruning of the other half; this time, however, cutting much closer to the stem, say from 4 to 6 feet. But everything must depend on the condition of particular trees. Plums, Apricots, and Peaches it is best to cut quite round, 10 to 12 feet from the stem, and if the shoots are thickly placed and weakly the least promising of these should be cut out. These remarks apply of course to large trees.

With regard to younger trees, say those of twenty years of age, which continue in an unfruitful condition, the mere cutting back of half the roots to 3 feet from the stem in the case of Apples, and to 6 feet in the case of Pears, may bring the tree into bearing. However, if canker is present, it may be as well to cut back the stem and not root-prune until after two or three years have elapsed, when both canker and unfruitfulness will disappear. The next year should see the root-pruning process completed. Some seasons it will be advisable not only to cut back the main roots previously left uncut, but also to cut a little further out from the stem round the first cut portion. This will hasten fruit-bearing very much. With regard to young trees I find it necessary to continue root-pruning. The trees may be left for a few seasons, but nothing is gained in any way, as the fruit deteriorates and the check is of course greater than when an annual or biennial cutting round takes place. If the shoots are kept fairly thinned there will be no gross wood made, but strong firm and freely studded with buds. Plums are especially liable to make a few very strong growths. I have seen these left alone, pinched, or broken clean off, or cut back; but neither of these—some good and some bad—practices is to be compared with attention to the roots, both as a check and as a hindrance to this habit.

It must be pointed out, however, that root-pruning in whatever form can never be perfectly successful unless other cultural points are at the same time remedied. For instance, pruning may be required to be modified. Some seasons the knife may hardly be needed at all, in others pruning may be a necessity. It is all a matter of judgment. Then an important matter too often neglected lies in allowing trees to carry too heavy crops. I find comparatively few people with whom I come in contact thin hardy fruits. Now it is good paying practice to do so, and in the case of old trees newly root-pruned which may set a crop of fruit, it is of the first importance that a very small crop should be left not to burden the tree. It may be said, however, that a heavy mulching of dung will carry the tree through. That I believe to be an absolute mistake. Dung as a fruit producer is a fallacy, and the

mere mulching of the ground will not have the desired effect. Bonemeal, lime, muriate of potash and superphosphate of lime are the kind of manures which produce fruit and fruitful trees of the highest excellence. Artificial manures based on these should have the preference to others when purchasing for this purpose.

But there will always remain a few trees which do not come up to others in healthiness, in fruitfulness, or in the good quality of the fruit. The simple remedy is to head over, regraft with good kinds, or else destroy. Trees may be root-pruned with safety up till January, but October is the better month, and in some cases August and September would be preferable.—B.

HARDY SHRUBS FOR FORCING.

VIBURNUM OPULUS.

WHERE forced flowers are required during the winter and spring, the Guelder Rose cannot well be dispensed with. Large plants lifted from shrubbery borders and potted in autumn, certainly yield quantities of flowers. But we have not found shrubs of this nature the most useful for yielding a succession over a lengthened period; in fact, large specimens are useless for any other purpose. This is not all, for unless large numbers are grown, the time comes when those in outside borders are unfit for forcing. After they are once dug up and forced, they need at least two years' rest before they are fit for forcing again. We strongly condemn robbing one part of the garden for the purpose of adorning another, when plants can be easily prepared that are more suitable, and can be used either for yielding cut flowers or for furnishing conservatories and other structures.

The most suitable plants for forcing are those in 5 to 7-inch pots, with three to six shoots 18 inches to 3 feet in length. When starting the culture of these plants for the first time, these anxious to have good specimens suitable for forcing next autumn should secure the requisite number of one-year-old plants at once—namely, those raised from cuttings inserted last autumn or winter. These on an average will have one strong shoot each and a quantity of roots. They should be placed into 5-inch pots; one good crock at the bottom will be ample, and the plants will do well in good loam and one-seventh of manure. The soil must be pressed firmly into the pots. We have invariably noticed that purchased plants never do quite so well as those raised at home. This is due mainly to the latter being lifted and potted while the foliage is fresh and green. With care in lifting, and attention in syringing afterwards, they make fresh roots and become partially established before winter. Purchased plants, even if bought while the foliage is upon them, are damaged in transit, and the leaves quickly turn yellow and fall. With care and good treatment purchased plants are useful the first season. If we had no old examples from which cuttings could be obtained we should purchase a double quantity of plants, potting the best and placing the remainder outside for lifting the following season.

After the plants are potted they can be plunged outside, covering the surface of the soil and rim of the pot with ashes. They may remain in this position until the approach of severe frost, when they can be pruned close back, leaving the eyes at the base of the young wood, and stood in cool frames. In spring plunge them in a sunny open position; if they can be covered with a frame for a time all the better. When once a stock of plants has been raised, cold frame treatment is unnecessary.

Two-year-old shrubs are better, as a rule, than those one year old; they generally produce a greater number of good shoots. When stock is raised at home, young plants or cuttings should be planted 15 inches apart between the rows, and 8 inches from plant to plant in the row. This gives them room to grow for two years without crowding. Any open sunny position will do for them; in fact, during the time they are being prepared previous to potting, almost any place will suit. For years we have been in the habit of placing them between rows of pyramid Apple trees. When they are left two years they need cutting close back during the winter after the first season's growth, and are lifted the following October, moderately early in the month—but this depends upon the season to a very large extent. When potted they are plunged where they are to be grown, in an open sunny position. The pots are placed sufficiently far apart so that they can grow the whole season without being crowded. It is important that light and air play freely amongst their shoots. This time the pots are buried during the process of plunging, the surface of the soil and rim of the pot being covered. The advantages of this method are not only the protection of the pots from frost, but labour is saved in watering. The plants may only need one or two soakings of water, unless the season proves an exceptionally dry one. In this case we have found it a good plan, after a thorough watering has been given,

to mulch with old manure or half-decayed leaves. Pruning is done any time during the winter or spring before signs of growth are visible.

Cuttings of ripened wood root freely enough if inserted any time after the end of October, but the earlier the better. The cuttings should be 6 or 7 inches in length, the top eyes being level with the ground after insertion. For some years we have practised rooting them in spring. Growing shoots are taken from plants that are forced and inserted in boxes of light soil, composed principally of leaf soil with a little sand on the surface. The cuttings are placed 2 inches apart, and if kept close and moist in the propagating frame they are not long rooting. They can afterwards be gradually hardened and allowed to grow in the boxes until autumn and then planted out singly.

After plants have flowered they should be cut close back and allowed to break into growth in a cool house or frame. If the pots are well filled with roots, which they are certain to be, whether one or two-year-old plants when they were first lifted, they should be shifted into 7-inch, and if encouraged under glass to grow for a time, they will be ready by autumn for forcing again. If they are hardened and placed outside as early as possible after flowering, very few of them will make strong well ripened shoots suitable for forcing, but they would do so the following season. When turned out after forcing they are severely checked, and one year's rest is necessary for them in which to recruit themselves. All the plants after forcing do not thrive equally well, and those that display signs of lagging behind are either planted out or thrown away, hence the necessity of raising a few annually to insure a healthy stock.

In some establishments a few examples in 10-inch pots may be found serviceable, and these may be prepared by placing them into this size after they have been forced and have started into growth in 7-inch. When they become crowded with roots in 10-inch pots, so much so that they refuse to make clean stout growth, they can be induced to do so by reducing their roots after forcing, and allowing them to grow without being cut back until autumn. If they are then pruned and treated the same as young stock outside, they will make strong growth again by the following autumn. It is much better to reduce their roots and give them fresh soil than to supply liquid manure. Only in exceptional cases would such a course be advised. As young stock is raised so easily and quickly, it is much better to pot on young plants than reduce the old ones and waste a season in recruiting them.—N. G.

(To be continued.)

CUTTING DOWN CHRYSANTHEMUMS, &C.

Now the Chrysanthemum season is over I should like the opinion of those who have tried the cutting down system, also the pinching system, or rather taking out the points to get the crown bud at the proper time for exhibition.

When I first adopted the cutting down system six years ago it proved a failure for exhibition blooms. The plants were certainly dwarfer and better for decoration or grouping, and for those purposes I would recommend it if carefully done. What I mean by carefully done is the plants should not be struck too early, or the wood would be hard and often wiry, and the plants should be well rooted in their pots, what would be just ready for potting, but they should not be root-bound; and, again, the soil should not be wet in the pots, but just moist, and care must also be taken not to cut them too low; there should be at least five or six good healthy leaves left below where they are cut off. I made mistakes in each of the above cases myself.

At one time I used to insert my cuttings in November. At that time the plants often throw good strong shoots, which are very tempting. But since I have left the propagation until the first week in January I have had more buds show naturally at the right time—that is to say, about the first week in September. Has the time of propagation anything to do with it? I think it has, but I will leave it for able persons to decide, if any will be kind enough to give their experience on the question.

When is the best time to cut down? In this district from the middle of May seems the most suitable time, commencing with the latest sorts and those which have filled their pots with roots, and all should, if possible, be completed by the end of June.

With regard to taking out the points of those which are not breaking naturally, I have tried some, commencing from June 20th until about July 14th, and the later date was too late.—J. L. B., *Leicester*.

WREATHS AND STANDS OF CHRYSANTHEMUMS.

THE accompanying illustration, sketched by our artist at the recent Exhibition of floral decorations in St. Stephen's Hall, Westminster,

FIG. 63.—A WREATH OF CHRYSANTHEMUMS.

affords some idea of what can be effected by a tasteful disposal of *Chrysanthemum* flowers with Grasses and appropriate foliage. Japanese varieties, orange or red, look well alone or in combination with white varieties for this work, especially under artificial light.

USEFUL CHRYSANTHEMUMS.

THESE, it must be noted, are for decoration and cut flower purposes. Some of them, doubtless, have been recommended in times past, but as there are always new readers, as well as some with new wants, I have no doubt they may be of use. I think the best of all is *Elsie*, a straw coloured reflexed Japanese variety, the only fault of which being its somewhat tall habit of growth. This is sure to be one of the most generally grown when it is better known. *Mrs. G. Stevens* is a small leaved good habited sort not unlike in the appearance of its bloom that indispensable sort *Sœur Malanie*, only the flowers are one-fourth larger, and what is termed old gold as regards colour. It is well worth growing. *Reverie* is now comparatively old, but it is still one of the best decorative varieties, with a close upright though free branching habit of growth with beautiful foliage, flowers of good size, and a tawny shade of red, and much better than *M. J. Laing*.

M. W. Holmes is even better than the above, but as it is earlier the two sorts require to be grown. Earlier than the above is *Roi des Précoces*, which we have grown for several years. It seems to be comparatively neglected, though one of the very best of the bright coloured sorts. A new sort is *Capucine*, of a pleasing orange shade and very dwarf habit. *Bettina* is also new, of much the same shade as *Source d'Or*, but of much dwarfer habit than that really good old sort. When the terminal buds are taken *Val d'Andorre* may be had comparatively late, and is most useful. *King of the Crimson* is also good, and comes in earlier than the above. *Dr. Sharpe* when first open is also fine. Of yellow varieties *Mrs. Dixon* and *Mr. Glenny* are still among the very best. There is no difficulty in securing three to five dozen fine blooms on each of these, and if the buds are left unthinned the number is very great. *Chevalier Domage* is also good, *Phœbus* excellent, and *Peter the Great* when well thinned has not as yet been excelled. *Alice Bird* is a light shade, but not, I think, so good as some others.

Among white varieties are *Mrs. Rundle*, extra fine; *Elaine*, perhaps the best; *Mdlle. Lacroix*, very good; *Jeanne d'Arc*, good when well grown; *Condor* I expect will prove one of the best of the medium late varieties; *Mrs. Forsyth*, dwarf, free, and good; *Felicity*, also good. All these sorts give much better returns than does the cultivation of a large number of varieties, keeping in view, of course, the supply of a large quantity of good flowers from a limited number of plants.

Of outdoor sorts not one has as yet surpassed *Précocité* for a good yellow, early, and continuous in flowering. *Fred. Pélé* is the best of the darks, and *Madame Desgrange* of the whites. The newer varieties have not given the satisfaction I expected. *Leoni Lassali* is some-

what of the same shade as *Elsie*, but lacking its attractiveness. Another season I hope to be able to give these a better position than in the past. *La Vierge* should be grown in every collection, and very neat is the dwarf yellow *La Petite Marie*.—B.

FUNGUS ON PEACHES.

YOU were kind enough to measure the Peaches I posted to you a short time since and to speak approvingly of them. As I then stated, they were gathered from large newly planted trees which had the three previous seasons been attacked with fungus, thereby causing the fruit to be useless. I will give for the benefit of your readers who may be placed in such a position as I was a full description of the treatment which proved so satisfactory. I know of two places in this neighbourhood where Peaches are grown largely, and the gardeners are trying to eradicate this same destructive disease, but up to the present their efforts have proved fruitless. I hope they are diligent readers of this valuable Journal, so that they may follow my practice and reap the same beneficial results.

I have two houses in which the trees have been attacked with this fungus. One, which I will call the large house, is 60 feet by 12 feet, and the small one is 40 feet by 12 feet; they are lean-to's and face due south. The trees are trained on the back wall, and there are two rows of pyramids in pots along the front. The trees in the large house were on the wall before the house was built, but I have never heard of any disease attacking them previous to the house being placed over them. In the small house the trees were all fresh planted, and those in pots obtained from a nursery. I mention these facts so as to make the case as clear as possible. I must necessarily give a rather long account, for I have had to battle against this disease for three years. I may also state I have sent leaves, fruit branches, and roots to some of the leading fruit growers of the day, and have also had them come to see and give their opinion on the whole matter, but not one of them suggested that a fungus was the origin of the evil. Some of them were confident it was at the roots, while others were equally as

FIG. 64.—A STAND OF CHRYSANTHEMUMS.

confident it was a scald by the sun's rays early in the morning before air was admitted.

I will now try and give a description of the fungus. It is on its first appearance so minute that it cannot be detected by the naked eye, but after about a week it is clearly visible, and the fruit looks as though it had been punctured by a pin; as the fruit grows the black dot becomes larger until it attains the size of a pea, and then you can see plainly a little white speck quite in the centre of the black one, which remains stationary until the fruits have stoned; after this it spreads rapidly, and in many cases three parts cover the fruit, at the same time penetrates down to the stone, thereby completely spoiling the crop. It also attacks the leaves when they are quite young, and they appear as if scalded. The specks are so small that you can scarcely observe them, but as the leaves grow so do the specks until the leaf gets more matured, then the diseased part falls out and leaves them as though they had been perforated by shots from a gun. I have never observed a leaf that has been scalded to lose that part which has been burnt by the sun, but it will still remain as part of the leaf, therefore there is a material difference between a scald and this disease.

This fungus also fixes its spores on the young shoots, and if it should come in contact with the bud it quite destroys it. It is not much unlike a brown scale, and when the wood gets hard if the thumb nail is placed against it, it flies off, taking the bark with it. This is very destructive to the trees, for where they are subject to gumming this is a strong incentive to the complaint.

As I took charge of the trees when the fungus could not be detected, for it had not much hold the first year of their being under glass, at the proper time I had all the trees taken from the wall, and the house thoroughly cleaned, pruned, and dressed with the sulphur, soft-soap and soot, with a little petroleum added, and replaced in their former position. The dressing was in no way applied for a fungus, but was for the prevention of insects, but it had a most beneficial result. The trees broke well, the flowers set well, and everything went on in a most satisfactory way until the fruit was the size of small woodnuts, and then to my surprise I found when thinning a quantity with the black spots, as I have mentioned before. This state of things alarmed me, but on making enquiry I was told some of the fruit was quite spoiled the previous year. I had no other choice but to grow them through this season. I then determined to renew the border, taking this in hand in the month of November, removing all the old soil to within 2 feet of the stem, and replacing it with fresh cut turfy loam and a sprinkling of chalk.

Though the trees were grown steadily and were free from insects, I scarcely had one perfect fruit for table, although I had adopted the methods advocated by eminent fruit growers—viz., air drains, more top ventilation, and shading the glass; but still the disease rapidly spread, and in some instances almost denuded the trees of their leaves. I was now convinced the enemy was a fungus of some description, and treated the trees accordingly; cleaned the house as in the first year, cement-washed the walls with a good quantity of sulphur added, dressed the trees as before, but adding about a pint and a half bottle of mildew composition formerly made by the late Mr. John Bell of Norwich, and now, I think, sold by most nurserymen. I continued using this composition until the fruit was all well stoned, applying a wineglass to a gallon of warm soft water, and well syringing all parts of the house both night and morning.

Air was admitted abundantly both night and day, but knowing the Peach to be a native of a warmer climate, I gave them as much heat as possible this season. I am happy to say I have had a splendid crop of fruit this year, and the sample you approved was a fair one. I made a new border in the small house and replanted the trees, which have done equally well under the same treatment. The fruit sent to you was gathered from this house.—ALFRED BISHOP, *Westley Hall Gardens, Bury St. Edmunds.*

REINWARDTIA (LINUM) TRIGYNUM.

THIS old favourite in the autumn months is one of the showiest of warm greenhouse plants, and deserving of much more attention and extended cultivation than it at present receives. The flowers are bright yellow, an inch or more across, borne for the most part solitary in indifferent examples, but in well grown specimens they are produced in dense umbel-like clusters, and the flowers being produced successively the plants are well flowered, though the flowers individually are of short duration, over a period of a month to six weeks. A groundwork of these plants, with the scarlet bracts of *Poinsettia pulcherrima* rising above the glowing yellow of the *Reinwardtias*, is simply charming.

It is of the easiest culture. Cuttings should be taken of the strongest points of old plants, which may be cut back to furnish them in February, and placed in heat and inserted singly in small pots in April or early May, placing in a close propagating frame.

They will root quickly, and being inured gradually to the atmosphere of a stove or intermediate house they may be shifted into 6-inch pots when the first are filled with roots, and from these transferred to 7-inch, in each case allowing them to be fairly well filled with roots before shifting. The cuttings of course may be inserted around the sides of store pots, transferring them singly into small pots when rooted, and afterwards shifting to a larger size as advised. These make very useful plants, but noble examples are obtained by placing three plants out of the 3-inch pots into 8 or 9-inch pots, having them as near the centre as possible. The pots must be efficiently drained, and a compost of good fibrous loam torn up with the hand, the loam being preferably rather strong, with a third of leaf soil, and about a sixth of crystal sand intermixed. Pot rather firmly, and if a little soot or some approved fertiliser be added to the compost it will help the plants to a good start. Water carefully, but afford a full supply when the soil becomes dry and before the foliage flags. They never can have too much light after they leave the cutting quarters, everything depending on a sturdy, thoroughly solidified growth. Pinching should be frequently practised, say at about every 4 inches to 6 inches of fresh growth up to early August, and from that time they need plenty of air and all the light possible, as it is imperative the recently made shoots and the stubby growths that will come giving the umbellate clusters of bloom be thoroughly ripened for flowering. The plants should be watered with judgment, affording sufficient to keep the foliage good—i.e., to prevent flagging. If kept wet and in a close moist atmosphere they will grow finely with a fair display of solitary flowers later on through the wood being soft and unripened, which is not the way to see this plant at its best.

In late September place the plants in a house where they have ample light, and with a temperature of 55° to 65°, the night and day artificial heat respectively, and if given a little Thomson's or other artificial manure scratched into the surface with a stick the benefit will be seen in the flowers—their substance, brightness, and continuance. The atmosphere should be kept somewhat dry—rather no special means should be taken to supply moisture beyond a slight damping occasionally of dry surfaces, but in dreary November the weather is usually moist enough without any need of damping. In a cold and damp atmosphere they do not flower satisfactorily, but after they come into bloom the remaining flowers will expand grandly in a temperature of 50°.

After flowering the plants may be rested, keeping rather cooler and drier, and in February they may be pruned, placed in heat, and when pushed an inch or so be shaken out, repotted, and grown on through the summer. Old plants, however, are not nearly so strong and free as those raised from good strong selected cuttings. Red spider is sometimes troublesome—a clear indication of too dry atmosphere, which yields to the usual remedies, syringing being the best.—G. ABBEY.

STORING ICE.

ALTHOUGH storing ice cannot be called gardening, still, like many things only remotely connected therewith, the gardener has often to be the person responsible for the supply of ice, so that it behoves young gardeners especially to keep an eye on this matter, as it is frequently one of great importance in large establishments. The work being generally performed by the labourers, the chances are that the responsible man of the future—the young gardener of the present, to wit—will know less about the operations than his men unless he improves his present opportunities.

It may be urged that anybody can store ice, but it might with equal force be urged that any gardener can grow *Chrysanthemums*, and it must be admitted that there are two ways of performing that operation. That there are several methods of achieving fair results I am well aware. I have seen and tried several myself, and still feel that I have something to learn. There is the system of throwing scalding water over the ice, also that of salting it, both with a view of congealing it into a solid lump; although I must think that if it is properly pounded before it is shovelled into the house, and beaten as firm as possible after it is in, that salt or hot water is not necessary. There is also the system of using a little straw—merely putting a course loosely around the house as the work progresses, and that of tying it with three bands into bundles a little thicker than a man's leg and about 5 or 6 feet long, and packing these closely around. Although I cannot see that it makes any difference to the ice shrinking from the sides, the latter plan has the advantage of being much the cleaner and prevents many loose straws getting mixed with the ice, and is much quicker done, provided it is (as it ought to be) all tied up beforehand and stored away ready for the occasion.

Another point, and one I would like to get a little information upon from anyone who can speak from actual experience—viz.,

whether it is best to have the house hermetically closed when filled, or to have several grated air holes the size of a brick near the top, and not fill the passages with straw between the outer and the inner doors.

Independently of all these matters, it is well known that some houses are noted for keeping ice much better than others, not always on account of situation or exposure, but from causes which it may be difficult to determine. In some instances it might be a very simple matter if one could only find out what. I give an instance that came immediately under my own observation. A certain house had never been known to keep ice longer than about the end of July, and one man could give the experiences of half a century. Latterly it had fallen into disuse, when the estate changed hands, and it had to be tried again. On examining the drain it was found there was no trap. One was put in, and the ice kept as well as could be wished. A simple matter enough, but yet no one had thought of it during all those years.—H. C. W.

EUPATORIUMS.

MR. MUIR does well in calling attention to these useful decorative plants, and it is indeed a matter of surprise that they are not more frequently referred to in advertisement and other pages. Mr. Muir says they can be had in bloom from October until January, but the three sorts we grow continue in succession two months later than that date, but perhaps reference is directed more particularly to the shrubby *Eupatorium Weinmannianum*. It is strange, too, that such doubts exist as to the correct names of these *Eupatoriums*. In not one of the several gardens in which I have served were their varietal or specific titles known with certainty, nor have I been able to strengthen my knowledge by inquiry of many visitors from time to time. The autumn flowering variety is succeeded by the dwarf branching one, the sprays of which are not so pure in colour, nor do they produce such large spreading heads; still it is useful in providing material for the conservatory and for cutting in good succession, which at a dull period is of great value. It never grows tall under any conditions, but forms a flat spreading bush completely hiding the pot, and makes a splendid plant for standing in vases indoors on that account.

The last of the trio makes a tall upright growth, and have furnished us with its large pure white sprays for Easter decorations at a time when that festive season has been early in the year. The stems of this latter sort are glutinous, which recalls to my mind an exaggerated statement once made to me by a lady, to the effect that each time flowers were cut from this plant the use of a fresh pair of gloves was necessary. Whether this was true or not, periodical visits were paid so long as the supply lasted for church and house adornment, and their pure white heads command attention either on the plant or in a cut state. If I have made my case sufficiently clear, perhaps some reader may be able to give the proper names of these deservedly popular plants, and I am sure the information, if forthcoming, would be acceptable to many admiring readers of the esteemed *Journal*, in disposing of the confusion that has long since existed with regard thereto.

The two last-mentioned sorts are softwooded and of quick growth. Cuttings struck in spring make plants large enough for any purpose when planted out in open garden during summer; but the earlier blooming autumn varieties may be retained for two or three seasons or more with advantage for furnishing large conservatories, as the growth thus made is harder and less rapid in its progress and maturity. Plants retained in large pots form short stubby growths, and provide a complete mass of bloom; but some cuttings should be struck annually, as these give the largest heads of looser character, and are valuable for room furnishing.—W. S.

VEGETABLE GARDENING IN SCOTLAND.

CULTIVATORS in northern parts will be ready to endorse much of what Mr. Pettigrew said in his opportune remarks at the Horticultural Association's meeting held in Cardiff. However, we do not think it is necessary that there should be less vacant ground in Scotch gardens during the autumn or winter months, or any other period during the year, than in any English gardens, though a few things do much better and come into use quicker in the south than the north. We think that in any garden it is thoroughly discreditable to have much vacant land lying uncropped at this season of the year. We have not a yard to dig up at present, except a portion from which late Potatoes have recently been removed, and that could easily have been filled by transplanting Cabbage, thinnings of Spinach or Lettuce therein; but the space, being wanted for another purpose than vegetable growing, is now empty. Under these times of high pressure few gardens in any part of the kingdom can be manipulated only to supply one crop during the year. What Mr. Pettigrew asserts regarding calendars and instructions for southern cultivation only is absolutely true, and while we have half a

dozen horticultural serials weekly as reading material, there is not, as far as we can see, any help in calendars for the helpless Scotch for planting, sowing, or other kitchen garden management. We have never experienced such severe frost or hot sun in Scotland as in southern English counties, but think vegetable management easier in the north than in England. We cannot say much about climatic influences in the north of England, but have had fair opportunities of noticing for the best part of a quarter of a century what can be done in east, west, and south of England. Beginning as a boy in London market establishments, we had to witness varied methods of turning means to best account. Practice in the north should not be exceptional.—M. TEMPLE, *Stirlingshire*.

AT a general meeting of the ROYAL HORTICULTURAL SOCIETY, held on Tuesday last, in the Drill Hall, London Scottish R.V., James's Street, S.W., T. B. Haywood, Esq., in the chair, the following candidates were duly elected Fellows—viz., C. F. Barker, Mrs. Bovill, Mrs. Bernard E. Brodhurst, Edmund T. Chamberlain, Norman Cookson, Thomas A. Cotton, Walter James Green, Charles Holden, A. Wells Ingram, Mrs. Kemp-Welsh, James Lake, R. Veitch Mather, Commissary General Hy. Moore, John Brandram Morgan, George Newman, Frank Rich, Ronald A. Scott, David Storrie, S. Stubbs, and Robert Willan.

—EVENTS OF THE WEEK.—Preparations for Christmas are now occupying the attention of many persons, and the markets begin to afford evidence of a busy period. There is scarcely anything to record in the shape of business meetings, but one even will no doubt attract many horticulturists to London on the 19th inst. That is the annual dinner of the National Chrysanthemum Society, when Lord Brooke will preside, and such an excellent programme has been prepared that a large attendance may be expected.

—THE WEATHER IN THE SOUTH OF ENGLAND has been variable during the past week. Frost continued until Saturday, when there was a moderately heavy fall of snow, which, however, rapidly melted on the following day. Early in this week the temperature became much higher, but with clear weather frosts returned, and it was somewhat sharp on Wednesday morning.

—IT is announced that a series of HORTICULTURAL EXHIBITIONS will be held at the Royal Aquarium, Westminster, during 1890, as follows:—January: Midwinter Exhibition of the National Chrysanthemum Society. March: First Spring Exhibition. April: Second Spring Exhibition. May: Early Summer Exhibition. June: Grand Rose Show and Fête. July: Grand Summer Exhibition. September: Early Autumn Show of the National Chrysanthemum Society. October: Great Autumn Exhibition. November: The Centenary Festival of the National Chrysanthemum Society. Suggestions as to dates, suitable classes, schedules (which are now in course of preparation) are specially invited, will receive careful consideration, and be adopted as far as possible. For all information, apply to William Holmes, Superintendent Frampton Park Nurseries, Hackney, London.

—THE NATIONAL CHRYSANTHEMUM SOCIETY'S ANNUAL DINNER will be held at Anderton's Hotel, Fleet Street, on Thursday evening, December 19th, when the President of the Society, Lord Brooke, M.P., has promised to preside. The following are also expected to be present:—Sir Guyer Hunter, K.C.M.G., M.P.; Sir Edwin Saunders; Shirley Hibberd, Esq.; Walter Johnson, Esq., L.C.C.; John Lowles, Esq., L.C.C.; Edwin Sanderson, Esq.; C. E. Shea, Esq.; H. Veitch, Esq.; Rev. W. Wilks; J. L. Wood, Esq., &c. The Society's trophy, medals, and prizes awarded at the recent Exhibition at Westminster will be presented on the occasion. The musical arrangements are under the direction of Dr. J. F. Haskins, which is a sufficient guarantee for an excellent programme. Mr. Holmes requests that those intending to be present will let him know how many tickets they will require by Monday, December 16th. Dinner will be served at six o'clock precisely; the tickets will be the usual price.

—CHISWICK GARDENERS' ASSOCIATION.—A well attended meeting of this body was held in the Council-room at the Royal Horticultural Society's Gardens on Friday evening last, when Mr. J. Barry read an interesting paper on "School Gardens," advocating where pos-

sible the formation of small plots as gardens to our schools as a means of recreation and instruction for the children. Additional interest was imparted to the proceedings by the fact that Mr. George Mitchell ("One from the Plough") attended and gave his warm support to the various suggestions throughout in the address. It may be remembered that Mr. Mitchell was a member of the London School Board when first established, sitting for the Chelsea Division. One of the best discussions of the session took place. Mr. George Gordon, the Chairman of the Association, ably presided.

— PROFESSOR MARSHALL WARD is about to deliver at the City and Guilds of London Institute a course of six lectures on *TIMBER, ITS NATURE, VARIETIES, USES, AND DISEASES*. The lectures will be given on Monday and Thursday evenings at 7.30 (December 12th, 16th, and 19th, and January 23rd, 27th, and 30th). The object of the course is to explain as simply and clearly as possible, with the aid of numerous lantern illustrations, the nature, properties, varieties, and uses of the ordinary timbers used in construction, and to give an intelligible account of dry rot, and allied diseases of timber.

— WARE AND DISTRICT HORTICULTURAL MUTUAL IMPROVEMENT SOCIETY.—A meeting of this Society was held in Ware on Tuesday evening, the 3rd inst. This is the third successful meeting held by this young Society. A paper was read on "Hardy Fruit" by Mr. Wallis, which was listened to by an attentive audience. A discussion followed by the following members:—Messrs. Fulford, Brown, Smith, Phillips, and Ridg. A hearty vote of thanks was accorded to Mr. Wallis for his paper, and the meeting terminated with a vote of thanks to Mr. R. Smith for occupying the chair.

— VINES FOR SHADED HOUSE.—Will you kindly insert the following in the *Journal of Horticulture*. I am in charge of a vinery, aspect due north, the wall on the south being high enough to exclude the sun's rays from October till March. I am growing in it Muscat of Alexandria, Mrs. Pince, and Alicante. These do fairly well with the exception of Mrs. Pince, which fruits well but does not colour. I have now room for two more Vines in the same house, and should be glad of advice as to the best other sorts to grow in such a position. They must be late keeping. I should like to grow Gros Colman, but I am afraid it would be quite useless to plant one. A reply from a practical man will be much appreciated.—A. B. C.

— AT the ordinary meeting of the ROYAL METEOROLOGICAL SOCIETY, to be held at 25, Great George Street, Westminster, on Wednesday, the 18th inst., at 7 P.M., the following papers will be read:—"Report of the Wind Force Committee on the Factor of the Kew Pattern Robinson Anemometer," drawn up by W. H. Dines, B.A., F.R.Met.Soc.; "On Testing Anemometers," by W. H. Dines, B.A., F.R.Met.Soc.; "On the Rainfall of the Riviera," by G. J. Symons, F.R.S.; "Report on the Phenological Observations for 1889," by Edward Mawley, F.R.Met.Soc. As the draft list of officers and Council for the year 1890 will be prepared at the next Council meeting, it is requested that those Fellows who wish to suggest names for the new Council will send them in before 18th inst.

— THE WEATHER IN NOVEMBER.—November opened very mild and continued so, with the exception of the 5th, 6th, and 13th, until the 25th, when frost set in rather sharp, and continued to the end of the month. Rain fell on twelve days, the heaviest fall occurring on the 24th, when 0.24 inch fell. Total fall for the month 0.76 inch. Highest shade temperature, 60° on the 8th; lowest, 26° on the 13th, 28th, and 29th; lowest on grass, 21° on the 28th and 29th. Number of days at or below 32°, in shade 8, on grass 13. Barometer variable; highest reading, 30.70, on the 18th and 19th; lowest, 29.40, at 9 A.M. on the 25th. Garden spring running 16 gallons per minute on the 30th. I may mention in passing that on Thursday, December 5th, at 9 P.M., the barometer stood at 30.80, a height to which our records do not show an equivalent.—J. TUNNINGTON, *Ketton Hall Gardens, Stamford*.

— READING AND DISTRICT GARDENERS' MUTUAL IMPROVEMENT ASSOCIATION.—The usual fortnightly meeting of this Association was held on Monday at the British Workman, when a large number of members assembled to hear a paper on "Primula sinensis," by Mr. James Martin (Messrs. Suttons' able cultivator). A collection of Primulas, kindly lent for the evening by Messrs. Sutton & Sons, was arranged at one end of the large room, and made a grand display, giving evidence of the lecturer's skill as a cultivator of the Primula, and his ability to deal with the subject. The President (W. I. Palmer, Esq., J.P.)

spoke of the great improvement made in the Primula during the last few years, and also of the great pleasure it gave him to be present on this occasion. During the discussion which followed various questions were put to the lecturer, all of which were ably answered, and much useful information was disseminated.

— WE are informed that on the occasion of the visit of H.R.H. Princess Beatrice, Princess Henry of Battenberg, to Reading last Tuesday, Messrs. Sutton & Sons had the honour of presenting Her Royal Highness with a magnificent bouquet of Orchids, of which the Princess expressed her appreciation.

— MESSRS. FOSTER & PEARSON send us from Beeston a copy of their Sheet Almanack for 1890. It consists of twelve removeable sheets, with the days and dates in each month prominent, and a margin of reminders of seasonable work in gardening. It is useful for gardeners' cottages and offices, in many of which it will doubtless find a place, and be serviceable throughout the coming year.

— DIARIES.—We have received from Messrs. Griffith, Farran, Okeden, and Welsh specimens of their diaries for 1890. They embrace almost every imaginable size and form that can be applied to these useful works, some being suitable for the desk, the library table, and the pocket, while others are so mounted that they can be hung against a wall. Apart from their utility as records of coming or past events, they abound in a mass of information easily accessible, which is an everyday want.

— MRS. PEARSON GRAPE.—In the fine range of vineries of Mr. James McIntosh at Duncreevan, Walton-on-Thames, the crop of this Grape is the most satisfactory of all. The bunches are large, well-shaped, and full; berries fresh, firm, without signs of shrivelling, round, about the size of medium Black Hamburgs, and clear amber in colour, without rust or speck, except in one bunch immediately over the hot-water pipes. They are distinctly perfumed, the scent reminding of Lilies of the Valley, but fainter. The berries are fleshy, rich with an agreeable aroma, and Mr. Taylor regards Mrs. Pearson as the most delicious and satisfactory of white Grapes for Christmas use and subsequently; but it is fair to observe that it is not everywhere grown so well as at Duncreevan. Mr. McIntosh's many friends will rejoice to hear of his much-improved health; in fact, it would appear as if he had taken a new lease of life, and there is every reason to think he will enjoy his pleasant home and beautiful garden more than has been possible during the past few years.

— SCHIZOSTYLIS COCCINEA.—I have never seen this flowering so profusely as it is this season. We have about 200 large clumps of it. Some are growing at the foot of a south wall, others are planted on a north border. In both situations they are a most brilliant sight at this season of the year, when hardy flowers are so scarce. In addition to their free flowering qualities they are exceeding valuable in a cut state. I find them last a fortnight when cut by changing the water about twice a week, at the same time cutting off a portion of the foot of the stalk and removing any decaying flowers on the buds as the spike expands. The foregoing are, I think, sufficient qualifications to make it deserving of space in every garden. It is generally considered a half-hardy bulb, but here (south of Ireland) it is perfectly hardy, receiving no protection whatever, and never fails at this season to yield a bountiful supply of spikes. Now, after ten days of frost, on the 28th ult., hundreds of spikes are available for cutting, after meeting all house demands.—HANDY ANDY.

— WAKEFIELD PAXTON SOCIETY.—Programme of meetings for the fourth quarter, session 1889-90. Meetings are held at the Society's Rooms, Saw Hotel, Westgate, each Saturday evening, commencing at eight o'clock prompt. December 14th, 1889.—"Migration of Birds;" Mr. J. Gerrard. December 21st.—"Arboriculture;" Mr. James Reed, Batley. December 28th.—Musical Evening (Sale of Periodicals). January 4th, 1890.—"Reminiscences of a Visit to Canada;" Mr. W. Hampshire. January 11th.—"Winter Notes," Mr. G. Bott. January 18th.—"Mignonette for the Conservatory," Mr. J. P. Carter. January 25th.—"The Cineraria," Mr. T. Gartery, Rotherham (Sale of Periodicals). February 1st.—"The Water Flea and the Water Weed; a Talk about Life;" Mr. T. Tate, F.G.S., Leeds. February 8th.—"The Cultivation of Hardy Fruits," Mr. G. Hudson. February 15th.—"The Cultivation of the Cabbage," Mr. J. G. Brown. February 22nd.—"Behind a Postage Stamp," Mr. W. Pye (Sale of Periodicals). March 1st.—Annual Meeting.—G. W. FALLAS, T. GARNETT, *Hon. Secs.*

— WE regret to announce the sudden death of DR. W. R. McNAB. He died at his residence in Dublin on Tuesday morning, the 3rd inst. Dr. McNab was Professor of Botany in the Royal College of Science, Dublin, having succeeded Professor Thiselton Dyer, F.R.S. He was also Scientific Superintendent and Referee to the Royal Botanic Gardens, Glasnevin, under the Science and Art Department. He appears to have been in his usual health on Monday, and on St. Andrew's Day (Saturday) took an energetic part in the meeting and banquet held by the Scotch residents in Dublin. The remains of the late Professor were interred on the 6th inst. A long line of carriages followed the hearse, and prominent amongst the mourners were the Professors and other officials connected with the Royal College of Science for Ireland. The chief mourners were the Rev. John Goold, Glasgow, brother-in-law; Mr. James McNab and Mr. Ramsay McNab, sons of the deceased; and Professor A. C. Haddon, M.A., Dean of the Faculty, Royal College of Science. The general attendance included the chief men of science, arts, and letters in Dublin. The interment took place in Mount Jerome Cemetery. The Rev. J. D. Osborne, Presbyterian minister, conducted the burial service.

— AMERICAN BLACKBERRIES.—In the note from "South Wales," in the last issue of the Journal, the writer says he never could grow or find any of them to merit ordinary praise, and further that he could not hear of a good crop. As to the former, it is perhaps not altogether the fault of the Blackberry; and as to the two latter, had the writer paid a visit to Hummersknott, Darlington, the residence of Arthur Pease, Esq., during last October, he would have seen a crop of American Bramble that would have probably astonished him. These plants were planted, I believe, four years ago, and are trained up an iron fence, and always bear good crops; but owing to early frosts they, like the native varieties, do not always attain maturity. "South Wales" also advises those who like Blackberries to plant our native varieties. I should be pleased to learn if he or any of your numerous correspondents have done so, and with what results.—DE NOVA. [A fine English grown specimen of the Parsley-leaved Bramble (*Rubus lacinatus*) has been illustrated in this Journal, and we have seen several most praiseworthy examples of culture. Perhaps when our correspondent "travelled from Land's End to John o' Groat's" it was by an express train.]

— PRESTON AND FULWOOD HORTICULTURAL SOCIETY.—The monthly meeting of the above Society was held at the Castle Hotel, Preston, on Saturday evening, December 7th. Through the unavoidable absence of the President, Alexander Ellis, Esq., occupied the chair, and was supported by Councillor Harding and members to the number of about fifty, the subject for the evening being the Melon. "Its Cultivation in Houses and Frames" was the title of a paper prepared and read by Mr. Williams, head gardener, Penwortham Priory. The essayist treated his subject in a thoroughly practical manner, from seed sowing in thumb pots to the planting out in suitable composts, training, fertilising, and ripening of the fruit. The reader was a little in favour of the extension system, but during an interesting discussion which followed, it was urged that planting fewer plants at intervals, according to the requirements, was much preferred to having plants with fruits of various sizes and in different stages of development. The cankering and decay of the main stems, so prevalent with some growers, was considered to be the result of a too free use of the syringe in houses where the water does not leave the plants sufficiently to render them thoroughly dry for a few hours each day and night. A hearty vote of thanks was accorded the reader, and also the Chairman. Many interesting exhibits were also acknowledged by the thanks of the meeting. It is gratifying to note the ever increasing interest and support extended to these monthly gatherings.

— SCOTTISH PRIMULA SOCIETY.—The annual general meeting of the Scottish Primula and Auricula Society was held recently at No. 5, St. Andrew Square, Edinburgh, Mr. Alexander Milne, Edinburgh, presiding. Mr. W. Stratton, Broughty Ferry, the Hon. Secretary and Treasurer, submitted a report upon the third annual Show held in the Calton Convening Rooms, Edinburgh, last May. The Show, it was stated, had been in every way successful. Exclusive of the species and varieties sent in for exhibition, about 300 plants were staged for competition. Mr. Stratton's financial statement indicated that with the balance of £10 9s. 6d. from the previous account, the year's income amounted to £37 5s. 6d.; while, on the other hand, the expenditure for the year amounted to £29 15s., leaving a credit balance of £7 10s. 6d. The loss of £2 19s. on the year's working was largely due to the falling off in subscriptions, which showed a decrease of £6 18s. The entrance money, however, showed a substantial increase, the attend-

ance at the Show having been about double that of the previous year. On the motion of Mr. Robert Lindsay, Curator, Royal Botanic Garden, Edinburgh, seconded by Mr. James Grieve, Pilrig Park Nursery, Edinburgh, both reports were regarded as satisfactory, and adopted. A letter was read from the President, Mr. Cathcart of Pitcairnie, suggesting that next year's Show might be held in Dundee. The proposal seemed to find general approval in the meeting, but before deciding on the change it was decided to take the opinion of the members on the matter. The office bearers were re-elected, and it was remitted to the Committee to adjust the schedule for next year's Show, adding prizes for Daffodils or Narcissus. The Secretary said, in reply to a question, that if the meeting were to be held in Dundee there would be no difficulty in getting a local Committee, and that the nurserymen would be ready to give them every assistance in filling the hall, which was larger than they had hitherto had, and was well lighted. The Chairman, in moving a vote of thanks to the Secretary, said that the most of the work of the Society devolved on Mr. Stratton, and that he did it most ungrudgingly and heartily. The motion was heartily agreed to.

GROUPING PLANTS AND FLORAL DECORATIONS.

I HAVE read Mr. L. Castle's able article on "Lessons of the Past Season" with great interest, and I should like to add a few observations chiefly upon the troubles caused to exhibitors by the vague wording of schedules. With regard to the employment of foliage plants in groups of Chrysanthemums there is a danger unless it is made very clear that they would possess more weight with judges than the plants for which the classes are chiefly intended. I think it would be more satisfactory to exhibitors to have two classes, one to continue as they have been, and the other for a group of Chrysanthemums and foliage plants, not to exceed so many feet, arranged for effect, Chrysanthemums to predominate and to be the only flowering plants used. I am not sure if it would not be advisable and bring a better competition if the latter class took the place of the former as a trial. Of this I am certain, if there is to be only one class and no limit is given to the foliage plants, the judges will be puzzled, and the exhibitors too, and neither would be perfectly satisfied. I am also sure that some of the exhibitors of groups of Chrysanthemums have not a good collection of Palms and other foliage plants, then it follows that the best foliage group would be the most pleasing and more likely to win. Whatever is done make it definite; it will be more pleasant for all concerned.

This brings me to the other part of the article respecting the exhibition of devices in St. Stephen's Hall; and here I contend that, through the uncertain reading of the schedule, the classes have caused some discontent. First I will deal with the hall vase of Chrysanthemums with any kind of foliage; now, as an old exhibitor, I should always carefully avoid using grasses, for fear any exhibitor would object, as I think he would have a right to do. I know perfectly well what effect a few grasses judiciously used have in any decoration, and I am certain it was the grasses and not the Chrysanthemums that had most weight with the judges. I quite admit it was the best-looking stand on the table. In this case also let the schedule read, "A hall vase of Chrysanthemums with any kind of natural grasses and foliage, not to be dressed at the base, and the whole when finished not to exceed 4 feet in height;" you would then get a uniform exhibition, and place all the exhibitors on an equal footing.

Now I come to the last and most important exhibit, the class for devices, and I must congratulate the donors on the splendid display such small prizes brought; and I also think the Society would do well to encourage this class liberally, either as a whole as this year, or in separate classes, and also to make this reading quite plain to exhibitors. If grasses are to be admitted, say so; but do not allow any other flowers to be used. The National is a Chrysanthemum society, and it should not allow other flowers to be employed in such competition.—W. BROWN.

THUJA OCCIDENTALIS.

THIS, the American Arbor-Vitæ, makes a capital hedge, and is well suited for many positions, especially where not exposed to strong gales of wind. It answers better in partially shaded places than many other shrubs do, and with those who understand its nature and the kind of treatment necessary to make it accommodate itself to certain positions very pleasing screens may be formed to hide unsightly walls. I have seen such screens, and have dressed some of them. For hedges of this shrub to have a pleasing appearance they should never be clipped with the shears, as by doing so you give them a stumpy appearance, which it is desirable to avoid.

This Arbor-Vitæ is employed in many nurseries to form screens for giving shelter to plants while they are in a young and tender state, and for this few shrubs are better adapted when judiciously managed. They can be kept very thin and green down to the ground for many years, while they are devoid of that stiff and shorn appearance which most hedges have. They occupy very little space, and to prevent their roots spreading cut them with a spade at about a foot or 15 inches from the stem. By doing one side one year, and then the other side the following year, the roots will be kept from impoverishing the ground or from

injuring young plants which may be near to them. When planted against walls the leader and main branches as they grow should be fastened to the wall by means of iron staples passing round them and into the wall. When the Arbor-Vitæ is judiciously managed in such a position, and having all the unnecessary breastwood cut off with a knife, it has a graceful and Fern-like appearance, which is especially pleasing when the wind ruffles its feathery sprays; indeed, under the management of a person who understands how to train and manage the Arbor-Vitæ, it is so accommodating that it can be turned to many useful and ornamental purposes.—D.

CYPRIPEDIUM T. B. HAYWOOD.

THIS was obtained from a cross between *C. Drurii* and *C. superbians* (Veitchi), and has neat and pleasingly marked flowers. One of the characters of *C. Drurii* is preserved in a marked degree—namely, the dark central lines in sepals and petals, which in the hybrid assumes a purplish hue. The rounded dorsal sepal have also secondary smaller and fainter radiating veins of purple and

FIG. 65.—CYPRIPEDIUM T. B. HAYWOOD.

green on white, something in the way of *C. superbians*; the petals have numerous purplish dots at the base, and the lip is suffused with soft purple tint. Neither of the species named as parents have been much employed in hybridising. *C. Drurii* is one of the parents (with *C. niveum*) of *C. microchilum*; it was employed with *C. villosum* in the production of *C. Winnianum*, but these are not very well known. *C. superbians* was, however, employed with *C. Stonei* in the production of the famed *C. Morganæ*, and with *C. barbatum* in producing *C. superciliale*, also a handsome hybrid. On Tuesday last this *Cypripedium* was exhibited by Messrs. J. Veitch & Sons at the Royal Horticultural Society's meeting in the Drill Hall, James Street, Westminster, when an award of merit was granted by the Orchid Committee. In our sketch the flower is slightly reduced.

ANGRÆCUM HYALOIDES.

M. GODEFROY LEBEUF'S *Orchid Journal L'Orchidophile* for November contains an excellent coloured plate of the above-named small but charming *Angræcum*. It is depicted growing in a basket, and has a number of short racemes of flowers clustered round the base of the leaves. The sepals, petals, and lip are white, semi-transparent, and nearly equal in size and shape, being acutely tapering. The flowers are very small for an *Angræcum*, the racemes being only a few inches long; but the plant is a little gem, and is highly prized in several collections in this country.—C.

A FLOWER HOUSE.

WHERE Orchids are grown in large numbers there should be one house devoted to those in flower. Its size must depend upon

the quantity of plants grown. The temperature of the structure would suit all the various occupants if maintained about 55° at night, and a few degrees higher during the day would do no harm. When in flower these plants unquestionably look best tastefully arranged amongst dwarf-growing Ferns and Mosses. Perhaps no variety is more suitable for this purpose than the old *Adiantum cuneatum* and *Selaginella Kraussiana*. A few small Palms may also be employed with advantage, but these should be light, after the style of *Geonoma gracilis* or *Cocos Weddelliana*, or they are better dispensed with unless they are used as a background. When a groundwork of Ferns is employed few plants are needed to make a brilliant display. This can readily be accomplished now that *Calanthes* in variety are plentiful. Those that cannot spare a structure for this purpose might devote a portion of their conservatory to Orchids while a good number are in flower. Care is needed that cold draughts are not admitted or the plants carelessly watered while in this structure.

CATTLEYAS.

Examine and thoroughly cleanse all Cattleyas, as it is much better to do this work now than when they commence producing their flowers, or the formation of new growth and roots. White scale is very troublesome, and is often upon them when they are imported. The only means of cleaning them is by the aid of a sponge and a little softsoap. Infested plants should be stood as much as possible together, so that they can be attended to frequently.

THE TEMPERATURE.

Care is needed for the next two months not to maintain too high a temperature; keep it steadily at 60°, a little more or a little less according to the weather will do no harm. It is better during very severe weather to allow the temperature by morning to fall 5° than overheat the pipes; a dry overheated atmosphere is certain to prove injurious to Cattleyas. It compels the application of water to the plants more frequently than is good for them, and yellow thrips quickly appears, giving endless trouble. No more water is needed now than will keep the pseudo-bulbs and foliage fresh and plump. By no means should they be allowed to shrivel by the want of water. Damp the stage and floor of the house thoroughly, when a little extra fire heat must be used.

PHALÆNOPSIS.

These must be carefully watched for the next few weeks. Do not arrange them too close to the glass or they may be injured during severe weather; let them be 2 feet from the roof. Now they are kept dryer, and the atmosphere of the house also, thrips will attack them if there are any about. Examine the plants carefully at least twice a week, and the first trace should be destroyed at once by sponging with a weak solution of tobacco water. If these pests are allowed to become numerous on the plants they quickly destroy their foliage and are most difficult to eradicate. The best plan under such circumstances is to sponge the leaves daily. Strong measures that can be used to some plants cannot be practised with these without injurious results following.

VANDAS.

These, *Aerides*, *Saccolabiums*, *Cypripediums*, and others, should never be allowed to become so dry as Cattleyas and *Dendrobiums*. The material in which they are growing must never become destitute of moisture, as this is frequently the cause of the lower leaves turning yellow prematurely. Watch for scale, and remove it at once by sponging the same as advised for Cattleyas. Yellow thrips are the greatest enemy to these plants, and although they bear light fumigations without injury, we prefer to avoid subjecting them to this treatment as much as possible. They are generally attacked at the top first, and the best means we have found is to dust the plants well with tobacco powder. It should be washed clean from the heart of the plant and axils of the leaves three or four days afterwards.—ORCHID GROWER.

EVERGREEN OAKS.

IN the private grounds surrounding the residence of Mrs. Alured Denne of The Grange, Lydd, Kent, are some remarkable specimens of the Evergreen Oaks. The largest one is quite 50 feet in height and about 78 feet in diameter. The branches, which touch the ground, are of the same proportion at the top as well as the bottom, so that the tree is very noble in appearance. There are others of less age and size in close proximity to the largest with a 6 feet bole, as well as perfect in shape and health, and situated as they are on the east side of the mansion they form an excellent shelter from the east winds, which have a clear sweep from the sea across Romney Marsh. The girth of the large tree 3 feet from the ground is 16 feet and 6 feet from the ground several branches spring out, two of the largest measuring 5 feet round

at 6 feet from the body, but several large branches have been cut years ago to give room for those remaining.

Romney Marsh land has long been noted for its rich herbage. The soil is very dark, and in some places a good depth, being probably at one time a sea bottom, consequently leaving a deposit of a very rich and fertile nature. The trees above mentioned are growing in some of the best of soil, which is resting on a mixture of beach or shingle and sea sand, under which lies a thick bed of dark clayey soil though not of a poor nature. But not only do Evergreen Oaks thrive here, and also large trees of Acacias 40 feet in height, as well as Variegated Hollies, while against the house are fine plants of Roses 20 feet up the wall, while the windows are encircled by fine plants of the large-leaved Myrtle all in full health.—THOMAS RECORD.

SOME USEFUL PLANTS.

THE following is a list of plants that I have found serviceable during the present and recent seasons:—

GLADIOLUS.

Dr. Bailly, a glowing soft scarlet, is going to prove one of the best. Also very fine is Panama, another of the 1888 varieties. Snowdon, an English raised variety, was exhibited in fine form. I have not yet secured this sort, but evidently it is one of the very finest. Enchanteresse has again been fine. Amitié, one of the soft shaded sorts, is one of the hardiest and also one of the grandest kinds. Indispensable also are Dalila, M. A. Brongniart, Sultan, Penelope. Shakespeare, Ondine, white, with soft violet markings, a lovely sort; Matador, Grand Rouge, Bicolore, Panorama, Flamboyant, very bright, Horace Vernet, extra bright; Diamant, very pretty; Baroness Burdett Coutts, Crépuscule, Eugène Souchet, rose, beautiful sort; Opale, soft, fine; Pasteur, extra fine soft rose; Pyramide, Sceptre de Flore, Fra Diavolo, very fine; Lady Bridport, are all sorts which are of free healthy growth, and should be grown by all who admire these highly decorative flowers. I was able to flower Duchess of Edinburgh this year; a single corm I procured from Dicksons, Chester, was cut in four, and gave three spikes. For northern gardens I should not recommend it, being rather late to be useful. I wonder why brenchleyensis is not cultivated more generally. It is certainly one of the best hardy flowers, cheap to buy, and the best of decorative flowers. Bossuet, crimson; W. E. Gumbleton, Lafayette, Lamartine, Lemoinei, Alsace, Sceptre d'Or, bright yellow; Etendard, A. Chenier, soft; Etoile, very beautiful, belong to Lemoine's hardy hybrid section, and all worth growing. Cultivators of hardy flowers must be on the outlook for the new hybrids originated by M. Lemoine, and which he has christened G. Nanceianus. Nine varieties are offered, two of which have already received first class certificates from the Royal Horticultural Society. The best appear to be President Carnot, P. Duchatre, Comte H. de Choiseul, and Maurice de Vilmorin.

CARNATION MRS. REYNOLDS HOLE.

In the Journal some months ago this variety had a rather bad character given it. I had a bed of it, and with me it proved one of the strongest and freest flowering sorts, and such as these are worth getting hold of when so many varieties without a constitution are to be had. I find it strikes quite easily from cuttings, though, of course, the strongest plants are from layers. Germania also did very well, though much of the bloom was damaged by damp and rain. In a good season this will prove one of the best of Carnations. It also strikes at any time from cuttings, and a stock of plants can be quickly run up. I am growing several dozens for spring flowering. For the latter purpose one of the very best sorts is Comtesse de Paris. The flowers are very large, and of a silvery glistening tone of white. A very beautiful sort, a sort I had last year, named Mdme. John Benary, and which is also good for spring flowering, can be highly recommended. It belongs to the fancy yellow ground section, and is beautifully flaked with rose. Good blooms are nearly 4 inches across.

PENTSTEMONS.

During the past few years some remarkable varieties have been introduced. The spikes are long, the individual flowers very large, and the coloration most attractive. A dozen of the best are Screnade, Vesuvius, Gyp, A. Daudet, Mdme. Dieulafoy, Melinite, Derviche, Director Braumuller, Orphée, Turban, Olivier Pain, and Paul Bert.

A GOOD BEDDING CALCEOLARIA.

This I had last year without a name. It is dwarf habit, the dwarfest yellow sort I am acquainted with, and about 3 inches less tall than Golden Gem; the flowers three times the size of that variety, and of a peculiarly soft shade of lemon yellow. I consider it one of the greatest acquisitions among flowering bedding plants. It certainly was the finest throughout the season here, and I have seen it elsewhere equally noteworthy. It has, I believe, been named Lemon Queen.—B.

MR. RICHARD PARKER.

"PARKER OF IMPNEY" is an association of names which have been familiar to most visitors to Fruit and Chrysanthemum shows of late years, and to all readers of garden literature. When Mr. Parker first came to the front as an exhibitor of Chrysanthemums and the winner of

chief prizes in good competition, his success created a feeling of wonder as to whether he would be able to maintain the position he won. He has done so, one of his latest achievements being the winning of the greatest prize ever offered for Chrysanthemums, and this in one of the closest and keenest contests of the year—namely, the forty-eight bloom class at Birmingham. The achievement is the more noteworthy since it was the fourth consecutive year in which he won the chief prize in the great midland city, and always against first-class competitors. Also in three consecutive years he has won three cups at Sheffield, including the "National" for seventy-two blooms.

Perhaps that record of success alone entitles him to the distinction of being presented to our readers as in the annexed engraving from a photograph, though it is not the only claim, and he is not the less satisfied nor the less to be commended for receiving the chief prizes for collections of fruit in 1886 at the Royal Horticultural Society's Provincial Show at Liverpool, in 1887 at Regent's Park, in 1888 at the Crystal Palace, and in 1889 at both the last named Exhibitions, the former in June the latter in November.

Having been trained under Mr. J. Smith at Mentmore and Mr.

FIG. 66.—MR. R. PARKER.

J. McIndoe at Hutton Hall, where he was foreman for eight years, Mr. Parker's competency as a fruit grower is not surprising, but he certainly took the world by surprise in taking such a distinct lead with Chrysanthemums, and it is perhaps not generally known that the first portion of his gardening experience was gained under Mr. Adam Forsyth, the famous Chrysanthemum grower in the Brunswick Nurseries, Stoke Newington, and it will be conceded he has done credit to the teaching of his old master.

Born in 1856, Mr. Parker is still a comparatively young man, with, it is hoped, a long and successful career before him. Only a man of distinct ability in the different branches of gardening could have followed with credit such skilful men as Mr. M. Temple and Mr. C. Thomas at Impney. It is true he has advantages there that fall not to the lot of all able men, for the owner of Impney, J. Corbett, Esq., M.P., is both wealthy and generous, and provides the requisite means for the high maintenance of his beautiful home surroundings.

Mr. Parker is now engaged in carrying out a considerable extent of landscape gardening—terrace extension at Impney—from plans of Mr. W. Goldring, so that Chrysanthemum growing has only a share of attention amongst various other claims on his time. He values highly the assistance of his foreman, Mr. Charles Crooks, and speaks of him as a first-class man, waiting for a position in which he can display his skill

as an industrious all-round gardener. Thus it will be seen Mr. Parker is not above admitting his indebtedness to a good master and a good man for the success he has attained in the discharge of his duty.

PROBLEMS IN CHRYSANTHEMUM CULTURE.

[A Paper read by Mr. J. Wright at Hull, November 21st, 1889.]

WHILE exhibitions of Chrysanthemums have done more than all else besides to popularise the flower that brightens, as no other flower can brighten, the proverbially dull month of November, something more appears needed for rendering those exhibitions completely satisfactory to those who so laudably and so ably share in producing them. I know of nothing more gratifying nor encouraging than the efforts that are made in various parts of the kingdom by gentlemen who have *not* been trained as cultivators, devoting a portion of their time, and not a small portion either, in producing the floral gatherings which afford delight to thousands who inspect and admire them. This action on the part of those who engage in it is most praiseworthy, and the business capacity thereby brought to bear in the formation and management of Chrysanthemum societies cannot be over-estimated. The response that is made by men who *are* cultivators is also gratifying—creditable to themselves and generally appreciated. I am convinced that nowhere else in Europe are Chrysanthemums so well grown as in this country, yet we are not satisfied. There is an old adage which says, "Much wants more." It is true as applied to many engagements of life, and certainly in respect to the cultivation of a flower that so well repays for the skill that is exercised in its production. The aim is ever for excellence, and still greater excellence. In the endeavour to attain an ideal standard impediments are met with that can only be removed by a combination of effort, each doing what little he can in adding to the common store of knowledge; and we may hope that by the aggregation of ideas we shall be able to take a step in advance yearly, and feel that we are treading on firm ground, thereby not only maintaining the position we occupy as the foremost Chrysanthemum-growing kingdom in Europe, but making sure, as far as possible, that our well-won supremacy will be sustained.

Under the general heading of Problems I have been requested to refer to a few of the difficulties which amateurs encounter in the prosecution of the work they so zealously engage in, but in which they sometimes fail to achieve the object of their hopes. In complying with the wishes of some good friends and ardent cultivators I find a wide field before me. What is a problem? The dictionary says—and it ought to know—that it is "a question proposed; a proposition; any question involving doubt and uncertainty." Now it so happens that I am relieved of the necessity of choosing certain propositions of that nature for discussion, because a few have been submitted to me in writing. These are—1, Time and methods of raising plants; 2, Timing of blooms in respect to cut-back and topped plants; 3, Potting, watering, and feeding Chrysanthemums; 4, The cause of damping in blooms; 5, The origin of sports. As dealing exhaustively with each subject would require five papers instead of one, each proposition can only be briefly stated in a form that will incite discussion, and I shall ask the co-operation of all—expert cultivators, and earnest, thoughtful amateurs—in endeavouring to remove some of the difficulties indicated, or, in other words, solving the problems proposed.

RAISING PLANTS.

I am convinced that many amateurs err in establishing young plants too soon, or say in November. Where the best conveniences exist for growing the plants steadily and sturdily the objection to autumn propagation largely vanishes. It is essential for the formation of the finest specimen plants, but not for the production of handsome individual blooms, except in the case of a few late varieties which require a long period of growth. When amateurs whose glass structures are limited, and consequently usually crowded with various kinds of plants, establish many young Chrysanthemums early in the autumn, they are extremely liable to be either "drawn" or "checked" during the winter months. In the former case they are weak to begin with in spring; in the latter, apt to form buds prematurely, and just when they are not wanted. Drawing is the inevitable result of overcrowding, while checks occur through the plants remaining too long root-bound in small pots, because of the absence of room in the most suitable portions for shifting them at the proper time. Most amateurs would do better by a limitation in numbers of autumn raised plants, and deferring the propagation till the turn of the year, when every succeeding night is shorter and day grows

longer—conditions that are essentially favourable for steady, substantial growth.

If short, robust root cuttings or suckers are inserted in February or March, the leaves never allowed to flag, yet never needlessly shaded, and the young plants kept moving without check of any kind, and in the most suitable positions, throughout their whole career, the larger flowering varieties especially will produce blooms quite large enough, and what is more the buds will, in all probability, be several days later in appearing than on plants raised three months sooner, and thus the naturally early sorts that so often come too soon and are "lost" before the shows, might be kept for them. As years roll round we hear more and more regrets about losing the best blooms of the Queen family with the "Alfreds," the "Wolseleys," the Jeanne d'Arc's, and others which have such an imposing effect, and count so heavily when in clean and good condition in the stands. I suspect not a few of those losses are the outcome of over-anxiety in working for blooms of extraordinary dimensions by early autumn propagation, and the influence this exerts on premature bud formation; and it is the same in respect to the naturally early Japanese. If amateurs were more generally to establish the late blooming varieties only in the autumn, and assign them the best positions through the winter, they would make the best of their space, and by striking the early varieties later than is customary the blooming of the two sections would be more equalised; but by treating all alike from the outset, starting them all together in the race, a close finish or simultaneity of expansion cannot be expected. Cuttings inserted singly in thumb pots in January for the midseason varieties, and a few weeks later for the earlies, will make better plants than if the cuttings were struck several in a pot two months sooner, and the growth subsequently checked by the necessary separation and breakage of the roots.

In striking the cuttings needlessly high temperatures should be avoided. A close case in a comfortable greenhouse is usually warm enough, ranging as it does from about 50° to 55°. Every ray of light should be admitted that the leaves will endure without drooping, and eventually air, while adequate moisture must be afforded. Every day during which cuttings flag may be counted as two days lost in after growth, for there is the actual loss by growth cessation, *plus* the loss of energy from the cutting or plant. For this double reason half-starving cuttings to death in endeavouring to strike them on dry open stages, or in too cold positions, should be avoided, for the first plan means exhaustion, the second stagnation. Steady, healthy, progressive movement from the first day to the last is the object to strive for, coddling, chilling, and checking being errors to be avoided in the career of the plants; and just in proportion as the right and rational plan is adopted, and the wrong evaded, so will the result be—sound, healthy examples of culture, capable of developing substantial blooms.

TIMING BLOOMS WITH CUT-BACK PLANTS.

This is a difficult question to deal with, and that is probably the reason of its formulation. As may be gathered from the foregoing remarks, I am a greater believer in "timing" the blooms by the insertion of the cuttings than by cutting back the growths; that is, when the finest exhibition blooms are coveted. No doubt very handsome blooms are produced by certain cut-back plants, and these plants, by their low stature and rich leafage, are indispensable for grouping and various decorative purposes; but, as a rule, larger blooms of the same varieties are produced when cutting the plants down is not resorted to. We have to bear in mind the object in view in considering this question. If it is for retarding plants on which buds show too soon, then topping the shoots, instead of cutting back the stems, is probably the better plan to adopt. Presuming that the production of crown buds at the right time is the chief point, and the naturally "early openers" form their buds towards the end of June, or early in July, as many do, the blooms would expand too soon, whereas if they were allowed to run on naturally to the next bud, this might be too late. It would be wise, therefore, not to wait till an early July bud actually forms, but take off the top of the shoot before the bud is visible, then the bud next following would come nearer the right time. When bud formation commences, growths push from the axils of the leaves below—the natural result of the cessation of extension of the main stem. To these the stem may be cut, taking up two or three for bearing the coveted blooms. If no bud forms early in July it is a good plan to top the plants. This is doing what the bud does—arresting extension, and accelerating the growth of bloom-bearing shoots or breaks, which, but for this aid, might come too late.

Some varieties, which are habitually too late, are found to come earlier by topping about the middle of May, taking up three shoots

and securing the crown bud when it forms. For the Queen family, and others that come about the same time, if dwarfing is desired, the end of May is a suitable time for shortening the stems, while the earlier sorts, such as the Beverleys, and others that expand about the same period, are put back by topping about the end of the first week in June. This is the result of experiments in the Midland counties, with an advance of a week added to render the periods indicated appropriate for the Hull district. It has been found that the Princess of Wales family, Prince Alfred, Lord Wolseley, John Salter, Refulgens, Jeanne d'Arc, St. Patrick, Mrs. J. Wright, Sarah Owen, Mrs. John Laing, Jeanne Délaux, E. Molyneux, and a few others, deteriorated after being topped in the blooms coming too small. It will be prudent for amateurs to proceed experimentally in this work, and in the first attempt to found their action on the appearance of the shoots at the end of June or early in July, proceeding as above indicated.

It may be mentioned that stout short-jointed cuttings of such varieties as Val d'Andorre, Avalanche, Elaine, Ed. Audiguer, Etoile de Lyon, and, indeed, several others, rooted between April and July the plants confined to one stem and one bloom from the crown bud are excellent for grouping purposes, the plants being flowered in 6-inch pots, and clothed with handsome foliage down to the soil. The cutting must not flag in the least during the process of rooting, nor the plants droop afterwards through omissions in watering, or they will be deprived of much of their beauty.

Anemone flowered varieties, except Lady Margaret and its sport, perhaps, Empress, afford the best quality blooms from terminal buds, and would consequently not be improved by either the cutting down or topping process. The very inexperienced may be informed that terminal buds always have other flower buds round them, crown buds never; but growths when permitted, as they should be in the section under notice, extend beyond these, terminating in a cluster of buds, the one at the apex being secured for the bloom, the others removed.

For practical purposes it may be said that crown buds must be chosen for developing the finest blooms in other than the Anemone section, and most of them should be set by the second week in August, a few of the slow openers a little earlier in the north-eastern counties, the quick expanders at the end of the month or the early days of September. As seasons influence the blooms, all the buds of the same varieties should not be "taken," as it is called (but "secured" is a more exact term) on the same dates, a little divergence being highly desirable in view of contingencies, as no one knows whether the Chrysanthemum season will be early, medium or late—two or three months in advance. Usually from three to four weeks elapse between the presentation of colour and the development of blooms, but varieties differ in that respect. I must close my remarks on the difficult phase of Chrysanthemum culture under notice, and leave others to make good what I have omitted on timing blooms by pruning or topping plants.

(To be continued.)

THE NATIONAL ROSE SOCIETY.

THE proceedings of the above Society at the annual meeting invariably induce a good number of members to attend, and so amongst those assembled on Wednesday, December 4th, in the Hotel Windsor, Victoria Street, I found myself, with some friends, a patient listener and on-looker. It is always surprising to witness the smoothness with which the business at these gatherings is disposed of. Where there is so little opposition or discussion it indicates either the pronounced ability of the Committee and officers, or considerable apathy on the part of the members. The former must be regarded as the case at the Rose Society's meetings, for though the members possess a preponderance of dignified solemnity, yet they cannot be regarded as apathetic. We must, therefore, take it the Hon. Secretaries so carefully consider all matters, and make such well devised arrangements, that the would-be critics, if any exist, are silenced. Still this meeting was not altogether devoid of several mildly exciting episodes, not the least being the erratic behaviour of the electric light intended to illuminate the apartment, but which did so in an extremely fitful manner, and finally left the assembly in complete darkness. This may have had a depressing effect upon the eloquence of the orators who had to propose the various resolutions, at any rate they nearly all confined themselves strictly to the letter of their texts. There was one exception to this rule, however, in the person of a reverend gentleman who proposed a resolution condemning "dressing Roses." He portrayed some of the

effects arising from this evil practice, and concluded with the astounding statement that some Roses had been seen so much altered in character by dressing that "they could not be recognised from Chrysanthemums or any other low flowers." This remark was greeted with a roar of laughter, in which some admirers of the "humble" Chrysanthemums ventured to join. But this burst of unwonted hilarity was followed by an almost painful silence, as if something was needed to restore the dignity of the assembly.

Another episode, however, gave a little life to the proceedings, for a well-known Colchester member arose to proclaim his disapproval of the Society's intention to offer prizes for Tea Roses at one of the Royal Horticultural Society's meetings. It is always a pleasure to see this gentleman assert his independent views, as he does invariably at these meetings, and it is fortunate for the Society that they possess a member who has the courage to express his opinions in opposition to such an array of skilled disputants. Although not entirely in accord with his views on this occasion, it must be admitted that his remarks cleared up some difficulties, and brought from a high official of the Royal Horticultural Society an assurance that members of the Rose Society would be admitted on presentation of their ticket. Our Colchester friend practically gained his point, and it was stated that the prizes would be open to amateur members of the two Societies.

Little else transpired to call for notice, but in the election of members of the Committee it was stated that one gentleman could not attend, and had sent his friend as representative to take his place. This induced a question from a famed rosarian as to whether it was desirable that two members of one firm should be on the Committee. The substituted candidate, however, volunteered an explanation, and he was subsequently elected. Whether this is a satisfactory mode of filling up vacancies in a Committee is open to doubt; it certainly would not be accepted by the members of some societies.

After the termination of the business certain of the members of a convivial turn remained to dine together, and I hear from a friend who was present that all retired at a comparatively early hour, much refreshed both by the viands and friendly comparison of notes, hopes, and prospects for the next Rose season.—A. K. B.

THE annual general meeting of the above Society took place in the Hotel Windsor on December 4th at 3.30 P.M., T. B. Haywood, Esq., in the chair, and the following members were present—The Hon. Secs., the H. H. D'Ombraun and Mr. E. Mawley, with the Rev. W. Wilks, H. A. Berners, F. R. Burnside, Alan Cheales, H. B. Biron, T. N. Flintoff, F. H. Gall, Capt. Christy, and Dr. Masters, with Messrs. H. Appleby, W. Rumsey, W. F. Cooling, H. W. Williams, G. Ramsey, C. E. Cant, G. Prince, G. Paul, J. Bateman, C. F. Barker, B. R. Cant, R. Bloxam, C. F. King, H. Wallis, F. Burrell, H. Turner, R. E. West, C. F. Hore, H. J. Pearson, T. W. Piper, F. Cant, and H. B. Lindsell.

After the transaction of the usual formal business the Rev. H. H. D'Ombraun read the following report, and the financial statement was submitted by the Treasurer, Mr. T. B. Haywood.

REPORT OF THE COMMITTEE FOR THE YEAR 1889.

THE Committee have once more the pleasure of reporting upon the Society's operations during the past year. The circumstances under which the Metropolitan Exhibition was held at the Crystal Palace were peculiarly unfortunate. Her Royal Highness the Princess of Wales had signified to the Secretaries her intention of visiting the Show early in the day. The Shah, however, having afterwards expressed a wish to be also present, and not being able to attend until the evening, this idea had to be abandoned; while the necessity of keeping the building clear for the Royal party compelled the Directors of the Crystal Palace to hold the Exhibition in a tent, to the great detriment of the Roses, and the great inconvenience of both exhibitors and visitors. The Committee can only hope that their Royal Patroness may on another occasion see their Exhibition at an earlier hour, and under more favourable conditions, and that it may never again be crowded into so limited a space. While referring to this visit of the Princess of Wales, they can but express their deep regret at the loss the Society has sustained in the death of their Vice-President, the Hon. and Rev. J. T. Boscawen, for it was mainly through his exertions and zeal that the patronage of Her Royal Highness was obtained. The Provincial Show at Sheffield proved less extensive than any held by the Society in recent years. This, however, was entirely owing to the earliness of the season, the first flowering being then almost over in many parts of England, and the unfavourable character of the weather immediately preceding the Show day.

The National Rose Conference held at Chiswick in conjunction with the Royal Horticultural Society early in July was undoubtedly the most noteworthy event of the year. It is only to be regretted that the attendance of visitors was not larger, for the exhibition held in connection with this Conference was one of special interest. Indeed, it may be many years before so unique and representative a collection of Roses and Rose species is again got together. The papers read, and the discussions thereon, were also both interesting and valuable. The Committee have made arrangements with the Council of the Royal Horticultural Society, by which every member will receive a copy of the report, containing not only the papers read at the Conference, but also valuable information respecting Roses and Rose growing, the result of returns sent in by the principal rosarians throughout the kingdom in reply to inquiries issued by the Conference Committee.

The Committee have had recently under consideration the growing practice of "dressing" Rose blooms at exhibitions. This they cannot but regard as prejudicial to the best interests of the Rose, and as likely,

if generally adopted, to bring discredit on Rose showing. They accordingly suggest that the attention of judges and exhibitors should in future be directed to the new regulation having reference to this objectionable practice.

They have again to mention the clashing of the shows of some of the affiliated Societies. There are, of course, considerable difficulties to be overcome, as so many local causes interfere, and particular days are in some cases absolutely necessary. Nevertheless, the Committee will again do all in their power to bring about as satisfactory an arrangement between the different Societies as these local considerations will allow.

Early in the year the authorised rules for judging at Rose shows were revised throughout by the Executive Committee, and afterwards printed in the Annual Report.

FINANCIAL STATEMENT.—The Treasurer is again enabled to report favourably upon the Society's financial position. The amount in hand at the beginning of the year was £41 2s., and now at its close there remains £84 5s. 3d. to carry forward to the next account.

ARRANGEMENTS FOR 1890.—The Committee has again arranged with the Directors of the Crystal Palace to hold the Metropolitan Show there on the first Saturday in July, the 5th. The Provincial or Northern Show will take place at Birmingham on Thursday, July 17th, under the auspices of the Birmingham Botanical and Horticultural Society, in their Gardens at Edgbaston. The last exhibition held there by the Society was in 1886, when over 3000 Roses were staged in competition.

As many of the finest blooms of the Tea Roses are often over before the Metropolitan Exhibition is held, it is proposed, if possible, to offer a few prizes for Teas and Noisettes at one of the Royal Horticultural Society's meetings towards the end of June.

The supplement to the catalogue of exhibition and garden Roses being now out of print, a special committee has been appointed to prepare a new supplement, which will be issued to members during the ensuing year.

MEMBERS' PRIVILEGES.—Subscribers of £1 will, as usual, be entitled to two private view tickets to the Society's exhibitions, and four transferable tickets admitting at the same time as the general public; while subscribers of 10s. are entitled to one private view and two transferable tickets. New Members will each receive a copy of the Society's Illustrated Catalogue of Exhibition and Garden Roses, together with one of the new Supplement; also a copy of the Report of the National Rose Conference held at Chiswick during the past summer.

Again the Committee has to record the good work done by their local Secretaries, and especially by one of their number, Mr. T. W. Girdlestone, who has recently secured for the Society a large number of new and influential members. It is scarcely necessary here to remind our local Secretaries how much the welfare of the Society is dependent upon their exertions.

BALANCE SHEET, YEAR ENDING 30TH NOVEMBER 18 9.

THOS. BURT HAYWOOD, *Hon. Treasurer.*
FRAS. WOLLASTON, *{ Auditors.*
J. D. PAWLE, *{*

The appended resolutions were submitted to the meeting and adopted.

- 1.—That the words "Half the members of this Committee to retire each year according to seniority, but to be eligible for re-election," be omitted from bye-law 6.
- 2.—That the first part of bye-law 7 be altered to read as follows:—"That the General Committee meet three times annually—in January to elect the Executive Committee; in March to consider the schedules for the year; and in November to make arrangements for the general meeting of the Society."
- 3.—That the following words be added to regulation 8: "Dressing Roses so as to alter their character is also prohibited. Also the insertion of any additional foliage."

The following officers and Committee for 1890 were also declared duly elected:—President, the Very Rev. the Dean of Rochester, D.D.; Vice-Presidents, His Grace the Duke of Portland, Right Hon. Joseph Chamberlain, M.P., Rev. J. M. Fuller, Robert Hogg, LL.D., James McIntosh, the Mayor of Birmingham; Hon. Treasurer, Thomas Burt Haywood; Hon. Secretaries, Rev. H. Honeywood D'Ombrian, Edward Mawley. General Committee: H. Appleby, R. N. G. Baker, J. Bateman, Rev. H. A. Berners, R. Bloxam, G. Bunyard, G. Burch, Rev. F. R.

Burnside, J. Burrell, B. R. Cant, F. Cant, Rev. A. Cheales, Captain Christy, W. F. Cooling, C. F. Barker, Rev. A. Foster-Melliar, W. H. Fowler, Rev. F. H. Gall, T. W. Girdlestone, W. J. Grant, R. Harkness, C. F. Hore, W. J. Jefferies, E. B. Lindsell, G. A. Marshall, M. T. Masters, F.R.S., G. Mount, Rev. F. Page-Roberts, G. Paul, J. D. Pawle, Rev. J. H. Pemberton, A. Prince, W. Rumsey, A. Slaughter, A. Turner, R. E. West, E. Wilkins, Rev. W. Wilks, W. H. Williams, and F. T. Wollaston. Hon. Auditors, J. D. Pawle and F. T. Wollaston.

The meeting terminated with the usual votes of thanks to the Chairman for presiding, to the Horticultural Club for the use of the rooms, and to the Committee and officers for their services during the year.

AMONGST THE ROSES.

THE weather during the first fortnight of November was well suited for garden work. It was taken advantage of by lifting all my dwarf Roses, a small collection forming the flower garden underneath the sitting room windows. The Rose trees occupying the beds, which at the first were composed of light, stony, unfavourable subsoil, were supplied at the top from time to time with dressings of virgin loam, good decomposed stable manure, and by these means, together with watching against insects and mildew, and copious syringings, and when necessary thorough waterings, my Roses have been generally satisfactory. At length the beds became too much above level of the grass, and the roots suffered accordingly drought.

Tempted by the mild still weather I resolved to renovate the beds, so after fresh labelling the Roses (about 120) and lightly laying them in where the roots might be protected from drying, or from frost, I had the soil dug out, using the upper surface as a top-dressing for herbaceous and other borders, and getting rid of all light and worthless soil. The bed thus emptied was replaced with a mixture of two-thirds of fresh loam and one-third spent cow manure well mixed. In these the Rose trees were replaced, with a surface dressing of manure and a sprinkling of ashes and soil over all.

Some weakly and unpromising or worn-out trees were eliminated and replaced by newer or more robust varieties. Delightful it is to the heart of a Rose lover to know he can count on some new blooms in the coming season. I am looking forward to Mrs. John Laing, Gloire de Margottin, Gloire de Lyonnaise, The Puritan, Earl of Dufferin, &c. Having small space one has to wait until there is a vacancy. I ought to say that I have brought all the Teas together by themselves instead of having them scattered about amongst the others, and I expect good results from the enjoyable occupation. I should have been unequal to this work myself, but I honestly shared in it, and am most grateful to the strong kind hands which really did the laborious part of it for me.

We have been engaged during suitable weather in laying out a new tennis court. It will be bordered on two sides by fruit trees. Some have been in the ground several years, and the Apple trees, Bramley's Seedling and Pearmain Mannington, bear well; the Pear trees take longer to fruit. Since the springs are more uncertain than ever, and the climate generally of a lower temperature, it is surely important to follow the advice given by local growers, who must know both soils and seasons, and plant only trees of robust fruit-bearing constitutions. Besides Irish Peach, which may at some future time furnish refreshment to the tennis players, Cox's Orange Pippin would come in too late. Then I mean to try Duchess of Oldenburgh, Lincoln Holland Pippin, and one or two kindred varieties. Some Crab trees would also be very ornamental. In short, dwarf fruit trees might often take the place of ornamental shrubs; equally, perhaps more, beautiful and more profitable.—A. M. B.

[We trust our correspondent will never lack the aid of "strong kind hands" to aid her in the work she loves.]

PROFITABLE FRUIT CULTURE.

WE have received a number of letters in reference to Mr. J. Wright's essay on the above subject, but some are too lengthy to be published in their entirety; in abridging them nothing in opposition to the teaching of the author has been eliminated.

MANY thanks for the very handsome and excellent essay on fruit growing. The more I examine it the better I like it.—A. F. BARRON, *Chiswick.*

I HAVE had a run through Mr. Wright's essay on fruit culture, and am very much pleased with it. It is a sound "multum in parvo," and cannot fail to be useful to all who may master its contents and have an opportunity of acting on them.—D. THOMSON, *Drumlanrig.*

I HAVE read Mr. Wright's prize essay, and truthfully assert that I have never before seen a subject treated in such a brief yet thoroughly instructive manner. The work is turned out in first-class style, and gardeners generally ought to possess a copy, for they will find nothing nearly so plain, reliable, and instructive in any other work of the kind. An extract from a financial paper is, I consider, misleading, as the prices of fruit named cannot be sustained. Those given by the author are nearer the mark, and I cannot pick holes in his own work.—W. IGGULDEN, *Marston.*

THE treatise on profitable fruit growing, although so concise, really contains all that is necessary, and if the advice in it be followed

it will justify the title. Being naturally rather critical, I thought it possible I might find in it something with which I might not agree, but as to treatment I have found nothing, and the only exception I can take is with reference to some of the lists of varieties to be cultivated, but even there I may be wrong, as the advice is addressed to small cultivators. My experience would not justify me in leaving out of a list of twelve Pears Comte de Lamy. It is a constant bearer, never varies in quality, which is that of the very highest kind. Comte de Flandres, Van Mons Leon le Clerc, and Zephirin Grégoire are superior to some named in the work. As to Plums, Jefferson is for all qualities, size, flavour, appearance, and free bearing, superior to any other. It makes the most delicious preserve, more delicate than Apricot. However, fruits vary in different localities, and my experience may be exceptional.—EDMUND TONKS.

I HAVE carefully read the prize-essay of Mr. J. Wright. It is full of detail, and contains more reliable information on fruit growing than has perhaps ever appeared in the same space before. Not only does the author say and illustrate what to do, but also what not to do. The illustrations convey the right and wrong methods of doing things in a small space and simple manner. On page 26, for instance, fig. 5 displays at a glance, without reading, how to plant Strawberries and how not to plant them. The method of planting, tying, and pruning Raspberries is also represented in the same excellent manner. Good methods of planting and pruning, and the reverse, are also instructively figured on pages 76 and 77. The work is written to aid cottagers and other small holders of land to grow fruit, and is just what is needed by them. But it should also be in the hands of every gardener. Young men especially should read it attentively, and they may learn more about hardy fruit growing than they frequently do after several years of ordinary practice in gardens. I regret that such a good and cheap little book was not in my hands twenty years ago. It would have saved me many blunders and mistakes since then.—WM. BARDNEY, *Norris Green*.

BOTH Mr. Wright and the Worshipful Company of Fruiterers must be congratulated on placing before the public such a wonderfully cheap and practical essay. Good fruit always pays, and if growers get a third of what is stated they may be satisfied. Living as I do in a fruit-producing county, I know the difficulties small growers have to contend with in disposing of what is termed soft fruit in small quantities, and jam factories or agencies for buying up fruit, such as are now being established at Pershore and a few other places, are very advantageous. There are capital selections of the various fruits to be grown, and they are equally profitable for growing in gentlemen's gardens. Plain and concise instructions are given on the different modes of culture. Mr. Wright commences his essay with the smaller fruits, such as Strawberries, Red and Black Currants, Raspberries, and Gooseberries, and then follows on with Apples, Pears, Plums, and Cherries. There are also chapters on manuring, grafting, thinning, gathering, storing, and marketing fruit. The Apples named are good, but how far the Broad-leaved Paradise stock will be suitable for bush trees on the majority of soils and districts remains to be proved. On strong soils I have found that the Ecklinville Seedling, Stirling Castle, Small's Admirable, Domino, and Keswick Codlin, are equally fruitful, and do not make over-luxuriant growth on the Crab stock. The illustrations, as to form of trees, planting, pruning, packing the fruit, with plans of gardens, are useful, and altogether we have a capital shillingsworth.—A. YOUNG, *Abberley Hall Gardens, Stourport*.

I SINCERELY hope my Irish countrymen will read well and inwardly digest the handbook on profitable fruit culture by Mr. J. Wright, issued by the publisher of the *Journal of Horticulture*, and which perforce places within the most convenient brief limits the most practical information on this increasingly important subject. In my rambles through this singularly favoured island—I mean by Nature and climate—I have often noticed one, two, three, or more acres of orchard attached to the farm houses here and there, but especially in Munster, and I regret to say in every instance those orchards are sadly neglected. Anything like root-pruning, winter dressing, removal of moss, dead branches, or top-dressings seems never to have been thought of. Generally those orchards are let every year at some small sum, barely sufficient in some cases to pay the rent and taxes. They are invariably Apple orchards—indeed, I never met a Pear, Plum, Cherry, or Damson preserve—and seem to be the remains of the old cider industry that existed beside the Suir and Blackwater and other favoured localities in the past century. In this locality I remember seeing two old cider presses a quarter of a century since beside the public road, where Apples were regularly purchased as they passed in carloads into town to make that wholesome and exhilarating drink. As to climate, I doubt if any part of England except the counties bordering the Channel has as mild or salubrious a climate for fruit culture. To-day (6th December), for instance, the open air temperature is 50° here, and I see telegrams notifying you have had six days smart frost around London and 10 feet of snow on the Continent in a more southerly latitude. The soil and climate of Munster cannot be excelled in the British Isles. Information is necessary, and a little more. That information, and that little more, Mr. Wright tells succinctly and in such a way that it would be impossible to do justice to it by summarising.

The book should be in the hands of every farmer—they are the

great middle class—every shop-keeper having a garden, and every owner of a villa and suburban residence where they can grow fruit. I can hardly suggest cottiers, as the great mass of them, unlike the same class in Great Britain, are only slowly emerging from poverty, and think it a good thing to have common food the year round. Since I read Mr. Wright's book I have been thinking how this valuable manual could be placed within the reach of the rising generation, and have come to the conclusion that the Board of National Education should be requested to place it on their list, so as to make it accessible to their teachers and the higher classes in the schools. This might be followed up by allowing some small result fees to advanced boys who answered best on the general subject. The rising generation must be looked to—the past are hopeless, and the present have different aims and objects that I cannot further refer to.

I think, too, the Commissioners of National Education when ordering their inspectors to report on teachers' school farms and gardens, should add some gratuity for those who grow fruit best. If the teacher understood and grew fruit, and gave an occasional lesson to his higher classes, using his own garden as an illustration, this would give a much-needed stimulus to fruit culture all over Ireland. One hundred pounds a year would do this—would pay the premiums and result fees. If we have a paternal government why not have a commencement made at once? Mr. Wright could readily append questions to the several chapters, to facilitate its use as a text book, if my suggestion, which I know to be practicable, were adopted.—W. J. MURPHY, *Clonmel*.

WHAT a capital manual the "Profitable Fruit Growing" is! The only thing to which I take exception is Adam's right leg, which is certainly out of drawing, and that I suppose is the fault of the Worshipful Company of Fruiterers.—EDWARD LUCKHURST.

[We wonder what grounds our correspondent has for questioning the accuracy of the anatomical drawing of the ancient limb by the "ancient" Company referred to for their heraldic device.]

ROYAL HORTICULTURAL SOCIETY.

DECEMBER 10TH.

THE last Committee meeting of the year is never expected to be largely attended by exhibitors, but the members of the several Committees usually assemble in good numbers to join in mutual good wishes for the coming year, and hearty votes of thanks to their respective Chairmen. The exhibits were not abundant at the Drill Hall, Westminster, on Tuesday last, and the central tables which have been required at every previous meeting were dispensed with, the side tables sufficing. Yet several interesting exhibits were contributed, and more certificates were awarded, especially amongst the Orchids, than at some gatherings when the exhibits have been more numerous.

FRUIT COMMITTEE.—Present: Sir C. W. Strickland, Bart., in the chair, and Messrs. P. Crawley, C. Ross, Harrison Weir, R. D. Blackmore, W. Bates, G. W. Cummins, G. Cliffe, W. Dominy, W. Wildsmith, G. T. Miles, W. Warren, G. Bunyard, J. T. Saltmarsh, A. H. Pearson, J. Willard, J. Smith, G. Wythes, J. Hudson, H. Balderson, F. Q. Lanc, G. Norman, Sidney Ford, and J. Wright.

Some Apples that had previously been before the Committee from Messrs. W. & J. Brown, Stamford, were again presented. Toogood's Seedling was considered too much like Golden Noble. Duncombe's Seedling and South Lincoln Beauty were not considered to possess qualities entitling them to any special award. A dish of very fine Apples bearing a general resemblance to Bramley's Seedling, yet sweeter, was sent from the gardens of A. H. Smee, Esq., and was considered worthy of further investigation. Mr. R. Doe, gardener to Lord Savill, Rufford, sent a dish of a seedling Apple, Beauty of Stoke, like a conical Blenheim Pippin, large, firm, and a variety of promise; considered worthy of further investigation. Mr. Ross, Welford, sent a dish of a seedling Apple, clear yellow in colour, remarkable in that respect as being a seedling from the Scarlet Nonpareil. It is above medium size, somewhat conical, tender, and of good flavour. It is named Atalanta, and met with much approval, and more information is wanted on its cropping quality. Mr. Ross also sent a very fine fruit of Smooth Cayenne Pine Apple, for which a cultural commendation was unanimously awarded.

The Rev. W. W. Wilks, Shirley, sent fruits of the "Tree Tomato" *Cyphomandra betacea*. They were acutely egg-shaped, 3 inches long and 1½ inch in diameter in the widest part, dark salmon in colour, firm, sprightly and agreeable, and possessing a brisk Tomato flavour. A cultural commendation was unanimously awarded, accompanied with a request that plants be grown at Chiswick. Mr. Wilks sent the following description of the plant with his exhibit:—

"TREE TOMATO.—The 'tree' on which the fruits shown have been grown is about 9 feet high, with a spreading much-branched head. The leaves when young are of a violet purple colour, changing with growth into a deep green. They are very large when fully developed. The blossom is precisely like a *Solanum*, being, in fact, to an ordinary observer, identical with that of the plant commonly known as 'Black' or 'Woody Nightshade.' It is an abundant bearer, the fruit ripening late in November and throughout December and January. The fruit when raw has a much firmer flesh than a Tomato, and is slightly more acid, but when cooked it is almost indistinguishable from the ordinary

Tomato. The plant has been grown throughout in a cool orchard house, from which only frost is excluded."

Mr. Miller, gardener, Ruxley Lodge, Esher, sent a basket of good Mushrooms from outdoor beds, and a vote of thanks was accorded. Mr. A. Harding sent from Orton Hall examples of very fine Brussels Sprouts, for which a cultural commendation was granted, and a recommendation that the variety be grown at Chiswick. Mr. H. J. Goodacre, Elvaston, sent a dish of excellent and well coloured fruits of the Ham Green Favourite Tomato, also good bunches of Lady Downe's Grape, and cultural commendations were unanimously granted for both exhibits.

A box of Coate's anti-incrustator was placed on the table by Mr. G. W. Cummins. It is a composition for mixing in water and placing in boilers for dissolving the fur with which they or the pipes may be encrusted. This, Mr. Cummins stated, it does in a week. The Committee had obviously no means of testing this mixture, and it was stated other articles were in the market for accomplishing the same purpose, and subsequently a gentleman remarked he could dissolve the fur in twenty-four hours.

The "Stott" manure and insecticide distributor was exhibited. It consists of a cylinder with cells for holding any kind of manure or insecticide that dissolves readily, the water being forced through the cylinder by hose attached to a water main or pump, and the solution is thus distributed by the pressure applied. Persons who have tried the "Stott" speak well of it, and it will in all probability be put to the test at Chiswick during the insect time.

This being the last meeting of the year a vote of thanks was proposed by Mr. Bunyard, and seconded by Mr. Harrison Weir, to the gentlemen who had presided at the meetings during the season, and acknowledged by Sir Charles Strickland.

FLORAL COMMITTEE.—Present: W. Marshall, Esq., in the chair, and Messrs. Harry Turner, Lewis Castle, H. Herbst, J. Walker, H. C. Leach, R. B. Lowe, C. Noble, J. Fraser, B. Wynne, W. Holmes, and F. Ross.

Sir Trevor Lawrence, Bart., M.P. Burford Lodge, Dorking, showed *Anthurium borfordiense*, a handsome seedling with rich scarlet spathes hard and rounded. Messrs. C. Lee & Son, Hammersmith, sent plants of *Bouvardia elegans variegata*, a sport from *B. elegans*, with scarlet flowers and leaves distinctly edged with white. Messrs. J. Veitch & Sons, Chelsea, exhibited a box of *Rhododendron* blooms of the javanicum hybrids, and it was stated that they were gathered from plants which had been flowering continuously since midsummer. Some members of the Committee also incidentally remarked, as proving the value of these *Rhododendrons* for long flowering, that few meetings for some years past had been without examples of these beautiful varieties and hybrids (vote of thanks). Two Carnations were also shown, one receiving an award of merit, the other, named Marie Louise, having fringed flowers, white tipped with purple. Several Orchids were shown and received various recognitions.

Messrs. H. Cannell & Sons, Swanley, had one of the brightest contributions to the meeting, a stand of dazzling Zonal Pelargoniums so useful for winter flowering. A purplish crimson Japanese Chrysanthemum of the incurved type, and said to be sweet scented, was also staged, together with a large single variety named Crimson and Gold, its title indicating the colouring. Mr. T. S. Ware, Tottenham, sent six pans of *Narcissus monophyllus*, having numerous white bell-shaped flowers. Mr. G. Masters, High Legh, Knutsford, showed an *Adiantum* named *inbricatum*, something in the style of *A. farleyense*, but with the pinnules deeply cut. Mr. Miller, gardener to Lord Foley, Ruxley Lodge, Esher, showed two boxes of fine *Eucharis* flowers (vote of thanks).

ORCHID COMMITTEE.—Present: Sir Trevor Lawrence, Bart., M.P., in the chair, and Messrs. J. O'Brien, F. Moore, J. Douglas, E. Hill, H. M. Pollett, C. Pilcher, H. Ballantine, H. J. Veitch, and Dr. M. T. Masters.

Mr. C. J. Catt, gardener to J. Charlton, Parr, Esq., Grappenhall, Heyes, Warrington, sent a seedling *Cypripedium*, which the Committee decided to be *C. lecanum*; also a fine variety of *C. bellatulum*, with a large deeply coloured flower. C. Ingram, Esq., Godalming, exhibited a plant of *Cypripedium Lathamianum*, of which we gave an illustration on page 175 in February of the present year. It is the result of a cross between *villosum* and *Spicerianum*, and partakes largely of the latter's characters (vote of thanks). Mr. Hill, gardener, to Lord Rothschild, Tring Park, exhibited a well grown plant of *Vanda Amesiana*, having a panicle 2 feet high and bearing twenty-three flowers (cultural commendation). Messrs. Sander & Co., St. Albans, had a basket of Orchids, comprising some very interesting plants, *Odontoglossum Wattianum*, *Cattleya O'Brieniana*, *Dendrobium bigibbum*, and its near relative *D. Slatterianum*, with several *Sophranitis* were capitally represented. J. G. Hodgson, Esq., Lythe Hill, Haslemere, was awarded a bronze Banksian medal for a plant of *Masdevallia towarensis*, having 162 spikes, 346 flowers, and 255 leaves, a surprisingly vigorous example of this useful Orchid. A well flowered specimen of the peculiar *Lælia bella* secured a cultural commendation for Mr. Cullimore, Kingston, the flowers clustered close to the pseudo-bulbs having white purple-tipped sepals, white petals, and a yellow lip. A vote of thanks also recognised the merit in a large variety of *Oncidium Forbesi* from E. O. Wrigley, Esq., Dukenfield, Cheshunt.

FIRST-CLASS CERTIFICATES.

Lælia-Cattleya Pallas (J. Veitch & Sons).—A hybrid between *Cattleya Dowiana* and *Lælia crispa*, with rather small sepals and petals

of a soft bluish tint, the lip broad, intense crimson, with a few gold veins in the throat, and undulated at the margin.

Cypripedium Niobe (J. Veitch & Sons).—A hybrid between *C. Fairrieianum* and *C. Spicerianum*, very interesting and distinct, showing at a glance the influence of the two parents. The dorsal sepal is much like that of *C. Spicerianum*, but somewhat more green at the base, veined with deep purple. The petals are undulated at the margin and strongly recurved, just like *C. Fairrieianum*, green, and a peculiar reddish brown tint. The lip is small, neat, and of a greenish hue.

AWARDS OF MERIT.

Cypripedium T. B. Haywood (Veitch & Sons).—A hybrid between *C. Drurii* and *C. superbiens*, illustrated on page 510 of the present issue of this Journal.

Cypripedium Galatea major (Baron Schröder).—A cross between *C. Chantini* and *C. Harrisianum*, the flowers large, the dorsal sepal edged with white, the centre heavily spotted with deep crimson, the lower sepals pale green with a few spots. The petals are purple, tinted and tipped with green, the lip having a purplish hue and polished surface.

Chrysanthemum Mrs. Alpheus Hardy (Pitcher and Manda).—A Japanese variety now well known to most persons interested in Chrysanthemums.

Carnation Winter Cheer (J. Veitch & Sons).—A dwarf, free-flowering variety, with scarlet flowers, likely to be useful for cutting and decorative purposes.

THE Council of the Royal Horticultural Society have lately had before them the very difficult work which always has to be done at a year's end—viz., determining on the names of three members of Council whom they will recommend (according to the provisions of the charter and bye-laws) for retirement in the ensuing year. The retiring members are not eligible for re-election, and when all have laboured so hard for the Society it is very difficult to say whose absence will be least detrimental. The same unenviable work occurs in the appointment of the several Committees, who have done such good and excellent work in the past year; for though in this case the retiring members are eligible for reappointment, the Council is of opinion that, as in their own body, so also in the Committees, a small infusion of new blood every year when it can be obtained is desirable, and there is probably no member of any Committee who would not be thankful for a year's rest from labour.

A vote has been taken on the question of changing the hour of the Fruit, Floral, and Orchid Committees from 11 A.M. to 12 noon, and in compliance with the wish of an overwhelming majority of the present members, the Council have determined to adopt the later hour for next year.

The following plan of arrangements, meetings, lectures, &c., has been drawn up and adopted. Other gentlemen besides those named have been invited to contribute papers, but it would hardly be courteous to mention their names until they shall have signified their consent. The meetings, &c., will be held in the Drill Hall unless otherwise stated:—

- Jan. 14th.—"A Method of Winter Gardening," Rev. W. Wilks.
- Feb. 11.—Annual General Meeting at 117, Victoria Street.
- March 11th.—"Hippeastrums" (*Amaryllis*), Mr. Harry Veitch, F.L.S., and Mr. James Douglas.
- March 25th.—"Saladings," Mons. Henry de Vilmorin.
- April 8th.—"Spring Flower Gardening," Mr. W. Ingram.
- April 15th, 16th, 17th, 18th.—Daffodil Exhibition and Conference at Chiswick. Readers of Papers: Mr. James Walker, Rev. G. H. Engleheart, Mr. J. T. Bennett-Poë, Mr. F. W. Burbidge, F.L.S., Rev. C. Wolley-Dod, &c.
- April 22nd.—Primula and Auricula Society's Show. "On Indian Primulas."
- May 13th.—"Hardy Spring Flowering Shrubs and Trees."
- May 28th, 29th.—Great Show in the Inner Temple Gardens.
- June 10th.—"Herbaceous Pæonies," Mr. Geo. Paul and Mr. R. Irwin Lynch.
- June 24th.—Exhibition of Tea Roses by the National Rose Society. "Hardy Herbaceous and Alpine Plants," Rev. C. Wolley Dod.
- July 8th.—"Cultivated Lilies."
- July 22nd and 23rd.—Carnation, Fern, and Selaginella Exhibition at Chiswick. Carnation Society's Show.
- 22nd.—Conference on Carnations. Readers of Papers: Mr. M. Rowan, Mr. H. Turner, Mr. R. Dean.
- 23rd.—Conference on Ferns and Selaginellas. Readers of Papers: Mr. J. G. Baker, F.R.S., Mr. C. T. Druery, Mr. J. Birkenhead, Mr. E. J. Lowe, F.R.S., Professor Bower, F.L.S., Mr. W. H. Gower.
- Aug. 12th.—"On Fruit Drying by Evaporation as Practised in America," Mr. E. W. Badger.
- Aug. 26th.—"Hollyhocks," Mr. James Douglas.
- Sept. 9th.—"Gladolus," Mons. V. Lemoine and Mr. J. Kelway.
- Sept. 23rd, 24th.—Exhibition of Dahlias and Grapes at Chiswick.
- 23rd.—Conference on Dahlias. Readers of Papers: Mr. T. W. Girdlestone, Mr. Shirley Hibberd, Mr. Walter H. Williams, &c.
- 24th.—Conference on Grapes. Readers of Papers: Mr. T. F. Rivers, Mr. R. D. Blackmore, &c.
- Oct. 14.—"On Crinums," Sir Charles Strickland, Bart.

Oct. 28th.—“Trees and Shrubs for Large Towns,” Dr. Masters, F.R.S.
 Nov. 11th.—“Chinese Primulas,” Mr. A. W. Sutton.
 Dec. 9th.—Ordinary meeting.

REVIEW OF BOOK.

The Journal of the Royal Horticultural Society. Part 3, Vol. XI., October, 1889. Edited by D. MORRIS, Esq., M.A., and the Rev. W. WILKS, M.A.

THE long expected issue of the Journal containing the papers read at the Rose Conference, report of proceedings, and analysis of statistical returns, has just come to hand as a substantial volume of about 440 pages. It is almost needless to say that it contains a great variety of interesting matter; but what will probably be looked for most especially is “Digest of Statistical Returns,” upon the preparation of which the Rev. W. Wilks has expended so much time and labour. This will amply repay for a careful examination, and though at first glance it appears a little complicated owing to the system of abbreviation necessarily adopted, a few minutes’ quiet reading enables anyone to grasp the idea so ably carried out.

One of the shorter papers, that by Mr. E. Mawley, on Rose stocks, is very instructive, and the following summary indicates his experience and views clearly:—

“1, That on a mellow loam of good depth, with porous subsoil, Hybrid Perpetuals on almost any stock will thrive and do well.

“2, That the seedling Briar has so far proved itself the best stock for the heavier soil and colder climate of my present garden.

“3, That the Briar cutting under similar conditions is but little inferior to the seedling. In fact, from the first it has been gaining on the latter. In the autumn of 1886, the plants on the cutting were credited with but five first places against twenty-seven for those on the seedling Briar, whereas the most recent examination accords thirteen first places to the cutting and twenty-one to the seedling.

“4, That the Manetti has proved itself in every instance inferior in a greater or less degree to the two other stocks, while in ten out of the thirty-four varieties in the experimental beds the difference is very marked. On the other hand, with thirteen other varieties there was little to choose between the three stocks.

“I find that Roses budded on these stocks flower, as a rule, in the following order. First come those on the Manetti, then those on the Briar cutting, and lastly those on the seedling Briar.

“For Tea Roses I have found the Briar cutting and seedling Briar excellent stocks. In dry seasons the latter has the advantage, and in wet ones the Briar cutting. The dwarf standard Briar also suits many Teas admirably, and some even better than either the seedling or cutting, and has the further advantage of keeping the blooms from getting splashed during heavy rains. It is of course, however, unsuitable for very cold districts, and is less enduring than dwarf Briars. The standard Briar also suits certain varieties of H.P.’s better than any other stock.

“The question of stocks is a more complicated one than would at first appear, for in order to obtain the best results the soil must not only suit the stock, but the Rose budded on it must work harmoniously with that stock. The character of the subsoil has also almost as important an influence as the surface soil. I may state in passing that there are a few kinds of H.P.’s which refuse to grow with me at all on any of the dwarf stocks I have mentioned.

“I had intended to touch on the subject of soils and their suitability to different stocks, but have thought it advisable, on more mature consideration, to confine myself entirely to a simple statement of my own experiences; for in discussing a matter of this kind I think you will all agree with me that one grain of fact is worth any number of pounds of theory. My experiments have, I trust, proved useful as far as they have gone. I can only regret now that they could not be carried out on a larger scale. I am pleased, however, to hear from Messrs. Cocker of Aberdeen, that they have during the last few years been testing stocks on similar lines to my own, and that they have arrived at some very interesting results, which will appear in the returns recently sent in to this Society. If other nurserymen and amateurs in different parts of the kingdom would only follow their excellent example, we should then at no very distant date be in a position to arrive at some more definite and satisfactory conclusions than in the present state of our knowledge is possible.”

As to the other contents of the book the following list will give the best idea of their extent and varied character:—“On Irises,” by Professor Michael Foster, Sec. R.S.; “the Strawberry,” by Mr. A. F. Barron; “Strawberries for Market,” by Mr. George Bunyard, F.R.H.S. The National Rose Conference.—Address by the Very Rev. the Dean of Rochester, D.D.; “Pruning Roses,” by Rev. A. Foster-Melliar, M.A.; “the Grouping of Garden Varieties,” by Mr. W. Paul, F.L.S.; “Roses since 1860,” by Mr. Geo. Paul, F.R.H.S.; “Decorative Roses,” by Mr. T. W. Girdlestone, F.L.S.; “R. Polyantha as a Stock,” by M. Viviani-Morel; “R. Canina from the Ural Mountains,” “the Botany of Roses,” by Mr. J. G. Baker, F.R.S., F.L.S.; “Modern Roses and Hybridisation,” by the Right Hon. Lord Penzance; “A New Classification of Roses,” by Professor François Crépin; “Rose Construction,” by Dr. Masters, F.R.S., F.L.S. “Notes on Australian Roses,” by Baron Sir F. von Mueller; “Note on New Indian Roses,” by Dr. George King; “Digest of Statistical Returns at the Conference,” by Rev. W. Wilks, M.A.; “Synonyms and Abbreviations used in Digest,” Notes on Digest of Statistics,” by Rev. W. Wilks, M.A.; “Summarised

Result of Statistics,” by Rev. W. Wilks, M.A.; “Note on Species of Roses shown at the Conference,” by Dr. Masters, F.R.S.; “Note on Books and Drawings of Roses at the Conference,” “The Origin of the Florists’ Carnation,” by Mr. Shirley Hibberd, F.R.H.S.; “Peaches and Nectarines,” by Mr. T. Francis Rivers, F.R.H.S.; “On Conifers,” by Mr. W. Coleman, F.R.H.S.; “On Pears,” by Mr. W. Wildsmith, F.R.H.S.; Proceedings of the Society, March 12th to June 25th.

ST. ALBANS AND DISTRICT HORTICULTURAL SOCIETY.

AN Exhibition of Chrysanthemums, fruits, and vegetables was held in the County Club hall on the 4th inst. As the Show was held principally in order to clear the Society of the debt incurred at the summer Show owing to the adverse state of the weather, but few prizes were offered. The chief of these in the cut bloom classes went to Miss Debenham. There was a keen competition amongst the cottagers in the vegetable class. The same remark applies to the preserved fruit class. The Show, although very late, was a capital one, and was largely made up with honorary exhibits. The exhibits staged by Mr. Beckett, gardener to H. Hucks Gibbs, Esq., must be awarded the palm; his cut blooms were exceedingly fine, especially the Japanese, the best being Volunteer, Etoile de Lyon, Ralph Brocklebank, Boule d’Or, Geo. Daniels, White Ceres, Pelican, Mrs. W. A. Harris, Mr. H. Wellam. The six trained plants were very good. He also staged a fine lot of vegetables and fruit. Handsome groups were staged by Mr. Whitelaw, gardener to Lord Grimthorpe; Mr. Sconce, gardener to J. S. Hill, Esq.; H. Slade, Esq., and Mr. Nutting, gardener to J. Blundell Maple, Esq. Messrs. Lane & Son, Berkhamstead, staged a fine collection of Apples, the following sorts being very fine—Peasgood’s Nonesuch, Mère de Ménage, Bramley’s Seedling, Winter Queening, Prince Albert, Worcester Pearmain, Annie Elizabeth, and Lord Derby. A good programme of music, instrumental during the afternoon, and vocal in the evening, was got through, and added to the attractions.

FRUIT FORCING.

PEACHES AND NECTARINES.—*Earliest Forced House.*—With the buds swelling and advancing for flowering the atmosphere must not be kept nearly so close, as it is important the blossoms come on steadily and have time to develop a strong flower, perfect in all its parts. A little ventilation should be given constantly, and above 50° it should be increased correspondingly with the temperature, but not allowing a decline below 50° in the daytime, sufficient artificial heat being employed for that purpose, and with sun an advance may be allowed to 65°, closing for the day before the temperature has receded 55°. A temperature of 40° to 45° is ample at night or in mild weather. When the flowers are advanced so that the anthers are showing cease syringing, but afford a moderate amount of moisture by damping available surfaces, as borders, paths, &c., in the morning and early afternoon. Avoid a moist, close, stagnant atmosphere with a high temperature at night. Make sure that there is no deficiency of moisture in the inside borders. If necessary supply tepid water or liquid manure. Moistening the surface is only a waste of time. Afford enough to moisten the soil through to the drainage. Weakly blossoms and failures in setting are often a consequence of moisture being given the tops of the trees instead of the roots. If there be a superabundance of flowers remove that on the under side or back of the trellis by drawing the hand contrary to the growth. It will materially assist the swelling and strengthen the remaining flower.

Second Forced House.—This may be the first in some establishments. It is that from which fruit is to be gathered in May or early June, and to which fire heat will be applied about the New Year. It must be closed at once, fire heat being only used to exclude frost, the trees being sprinkled in the morning and early afternoon, allowing time for them to become fairly dry before night. Nothing is so enfeebling as keeping the trees constantly dripping with moisture, especially at night. Do not allow the temperature to exceed 50° without full ventilation. Soak inside borders with tepid water or liquid manure, and protect those outside with dry leaves or bracken and a little long litter, allowing a slope to the front, so as to throw off cold rains and snow. Some tarpaulin or spare lights would be an advantage.

Succession Houses.—Proceed with the pruning, bringing matters in respect of cleansing the house and trees to as speedy a conclusion as practicable. If the houses have fixed roof lights ventilate to the fullest extent in all but very severe weather. It is much the best plan to remove the roof lights and expose the trees to the elements for the winter. Even the latest and unheated houses should be treated that way. We find the best results attend that method of procedure. Trees even that are liable to cast their buds, such as Noblesse, retain them, and

attain to a much finer development of flowers than attends trees that are kept constantly evaporating from the young wood through the time they are at rest by fixed roofs. The fogs, drizzling rains, and damp of November and December, with the drenching rains and snow, seem to suit Peaches, the trees being invigorated and the soil enriched.

PINES.—Judgment and considerable skill are required to maintain with limited means a successional supply of ripe Pine Apples throughout the year. The cultivator, with his tens or twenties, is often at his wit's end how to obtain fruit at the right time, but with hundreds of successions there is no difficulty in maintaining an unbroken supply of fruit. Where a supply of ripe fruit is required in May and June, which is the time when home-grown fruit is most in request, and the plants are not showing fruit, it will be desirable to select from those started last March, which have completed a stout growth and are now in a state of rest, such as show the best indications of starting into fruit when subjected to a higher temperature both at the roots and in the atmosphere. If the plants can be accommodated in a structure to themselves it will be an advantage, but failing such they should have a light position in a fruiting house. It is not desirable to start more plants at this season than are absolutely necessary, as the fruit will come up more readily a month hence and be much stronger. Continue former instructions as to temperature, &c., but in very severe weather a fall of a few degrees in the temperature is preferable to extra sharp firing, and wherever practicable a covering placed on the glass at such times will be desirable, being a saving of fuel and better for the health of the plants.

PLANT HOUSES.

Bouvardias.—Plants that flowered in early autumn and have since had a good rest by keeping them dry and cool, may now be started into growth. When good bushy plants are needed in one season from either cuttings of portions of root, it is important to make an early start. The whole of the old soil should be shaken from their roots, the plants potted in moderately small pots and started into growth in a vinery or Peach house, or in a temperature of 50° to 55°. Before potting them, however, if a stock is to be raised from root cuttings, a few strong roots should be taken from each plant. No injury to the old stools result from this treatment. The portions of root must be cut into lengths of half an inch and placed in the centre of 2-inch pots, just covering them with fine soil. If these are plunged in brisk heat in the propagating frame they will quickly start into growth and be out of the way by the time cuttings are ready or the busy season for propagating arises. The stools as well as the root cuttings may be potted in equal portions of loam and leaf mould, with the addition of a liberal quantity of sand. The stools, after being potted, should be dewed with the syringe only until they display signs of growing.

Lilium Harris.—Bulbs that were potted as early as they could be obtained have growth 2 feet high. Care is needed to prevent them drawing up weakly by maintaining a temperature of 50° to 55° at night, according to the weather, and with a little ventilation on all favourable occasions. Be careful not to overwater them, and watch for aphides, which usually appear at this stage in the tops of the plants. Slight fumigation with tobacco is the best means of destroying them, and this should be done directly they are observed.

Hydrangeas.—Plants that were rooted early in 2½-inch pots and lost their leaves before they were boused may now be placed into 5-inch pots, the bud only being above the surface of the soil. One good crook at the base is ample. Soil is which Cucumbers have been grown is suitable, with the addition of about one-third leaf mould. Press the soil firmly into the pots. The plants can then be started in a temperature of 50°. As soon as they commence growing place them close to the glass. Water carefully at first; this is important until they have commenced growing, when liberal supplies may be given. Old stools that are kept in pots and have been cut back may be potted when opportunity offers, and plunged in frames. It is a mistake to keep those for yielding good heads too confined at their roots. Strong heads are the best because from these the largest and finest trusses are produced. Puny cuttings only develop small flower heads.

Fuchsias.—A few plants that have enjoyed a complete rest may be pruned and started into growth. Shake them out and start in smaller pots, the same as advised for Bouvardias.

French Pelargoniums.—Old plants that were cut back and started in moderately small pots should be placed into a larger size. Use for a compost good loam, one-seventh of manure, and sand. Drain the pots well, and press the soil firmly into them. This will insure dwarf sturdy growth. Arrange these plants close to the glass, and give no more fire heat than is necessary to expel damp, and maintain a temperature of 40° to 45°. Young rooted plants in 3-inch pots should be given others 2 and 3 inches larger. The strongest can be placed in the last size. Grow these on under the conditions advised for old plants. The shoots of these may be pinched from time to time as they need it. Those for early flowering that were pinched in September must be kept close to the glass, and in a temperature 5° warmer. Those showing flower that were grown through the summer for this purpose should not be in a lower temperature than 60°. Admit air whenever favourable to prevent the plants drawing up weakly. Supply water carefully, giving no more than is really necessary to prevent flagging. Too much water causes the foliage to be spotted, and induces soft growth. Fumigate with tobacco if aphides appear.

Zonal Pelargoniums.—Those well prepared by being thoroughly ripened outside will continue to flower profusely if they are not overwatered, the atmosphere being kept moderately dry, and the tempera-

ture about 60°. During fine mild weather admit a little air daily. Remove decaying leaves, and give weak stimulants every time water is needed.

Cinerarias.—Late plants, now in 3-inch pots, may be placed into 5-inch pots, and kept in any position where they will be safe from frost. Small late Primulas may also be potted, and subject to the same treatment. Plants potted now flower most profusely late in spring, and are the best from which to save seed.

THE BEE-KEEPER

GLASS SECTIONS—THE PATENT LAWS.

ON page 454 "A Sussex Amateur" complains that I have not fulfilled my promise, and given the instructions I said I would on page 528 for December 6th, 1888, as to how to make the above, and he also asks for information concerning the patent law and the rights of patentees. For the first part, I must refer him to the Editor, to whom I sent the drawings and descriptions long ago. No doubt "want of space," caused by so many shows in summer, has been the cause of their non-appearance. If "A. S. A." cannot wait he can, perhaps, glean nearly all he wants from a Government Blue Book, published by the Comptroller of Patents, 25, Southampton Buildings, Chancery Lane, London, W.C., and sent post free for 2s. 6d. In writing ask for "Blue Book on Bee Hives, A.D. 1888, No. 7660."

Answering the other part, which I feel quite qualified to do, as it is a subject I have studied, I may inform him that a patentee owns the exclusive property in his invention. No one has a right to make, use, sell, or even handle, what he holds his patent on without his consent, except for *bona fide* experimental purposes. This is the only exception, so that he must not make for his own use. Everyone has a right to improve on, add to, or take from a patent invention, and get a valid patent on it, but he acquires no right to use his improvement without the consent of the original patentee. However, if terms are refused he can, under the Act of 1883, apply for a compulsory license, so as to enable him to work his patent, when the Court will fix the royalties and the securities.

In this country a patent is a grant from the Sovereign in exchange for a full disclosure of his invention. It is not granted as a matter of "right," therefore if an inventor first publishes his invention he cannot get a valid patent, because he has already parted with his equivalent part of the bargain. The only right that an inventor has is to keep his invention a secret, and if he decides on this course all the Courts in the country will protect him in his decision, and if he dies the secret may die with him, as was very often the case before the passing of the Patent Acts. This would be a loss to the community, so the Patent Laws were adopted in order that inventors should be induced to make their inventions public.

In the United States of America every inventor is entitled to a patent as a matter of right, and of which the law cannot deprive him, if he applies within two years of first making it public. Inventors there are thus allowed to publicly use or test their inventions before patenting them; but it often happens, if the invention is a valuable one, a host of claimants spring up, hence the Courts are occupied for years in deciding these claims, which cannot arise under the British system.

What is here known as "nine months' provisional protection" is really no protection, as anyone can make, use, or sell the article "protected" until the date of acceptance of "complete specification." What it really does, and what it was instituted for, is to give inventors the benefits given by the U.S.A., and yet be essentially British. Therefore it only fixes the "date," and an agreement on behalf of the Crown to grant a patent if completed within nine months, but which may be extended to ten months by paying £2 more. If the invention is kept secret in the meantime, the first application can be abandoned and a fresh one made; but should someone else have made the same discovery you can go on with the first and take priority over him.

"A Sussex Amateur" particularly wants to know how he can evade the patent rights on metal cornered glass sections. Now Mr. Editor, I do not feel inclined to side with anyone who would cheat an inventor of his just rights by any quibble or sophistry. He has as much right to enjoy the fruits of his labour and make the best he can of it as a market gardener or writer has of his labour. The Copyright Acts protect the latter for his whole life and seven years longer, or if he die within thirty-five years then such a length

as will make up forty-two years, and he is not obliged to be in any haste in registering his title, and when he does so the fee is only 5s. To take off a man's invention without his consent is as much stealing as taking a Cabbage out of his garden, but in law the offence is far greater and penalties are very much more than any J.P. can inflict on a common pickpocket.

I may, however, for the information of "A Sussex Amateur," say that I have seen the tin corners he refers to advertised as "patented" and "registered" as a "design." The latter only protects the "shape" of a thing, and cannot protect an article that should be patented. I thought of, and tried the very same thing some years ago, and discarded them; in fact, it was because I did not like the looks of these tin corners, and took them off to see how a section would look, when I found the comb was sufficiently fast to the glass sides to hold them together, and then set to work to contrive means of holding them in position until the bees fastened them together by means of their comb. Putting my sections together is now as simple and easy as building toy bricks. There is absolutely nothing used at the corners to hold them together. The glasses are cut on a very simple special board, and are bound to be exactly true to size, no matter how the glass used may vary in thickness, while in putting together the glasses support one another, making the thing as easy and simple as possible. No wonder, now it is being generally known, that hosts are jumping up claiming to have used the very same thing, yet some of them distinctly declared they could not guess how it was to be done when I said "nothing was used at the corners to hold them together, either visible or invisible, yet the glasses were all cut true right angles." I say, if they had known it they would have "guessed" at once and not have laughed at me, and plainly hinted I was humbugging them, but such is life and the experience of—
A HALLAMSHIRE BEE-KEEPER.

ERRATUM.—In my article last week at the bottom of the first column, page 496, 90° is a misprint for 95°; and Mr. W. L. Hutchinson should be Mr. W. Z. Hutchinson.—A HALLAMSHIRE BEE-KEEPER.

[Many of our readers will be glad to peruse the above interesting notes on the Patent Laws. In respect to the drawings referred to we intended having engravings prepared under the assumption that they would be serviceable to persons who desired to work from them; but as we find the method we intended to portray is patented, and as our correspondent states "no one must make the articles for his own use," he simply tells us it is of no use publishing the details in hand. He is quite justified in patenting anything the authorities admit is a distinct invention, and no one is justified in acting contrary to the law on the subject; and, further, we do not see on what grounds "A Hallamshire Bee-keeper," with his high respect for morality, can desire us to place temptation in the way of the world by publishing his drawings. The matter, therefore, remains still longer in abeyance.]

* All correspondence should be directed either to "THE EDITOR" or to "THE PUBLISHER." Letters addressed to Dr. Hogg or members of the staff often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post, and we do not undertake to return rejected communications.

Books (F. A.).—There is no work embracing all the subjects that your inquiry suggests, nor any periodical exclusively devoted to the question. There are small works treating on special subjects, but as you do not indicate the object you have in view we are at a loss which to mention. (B. D.).—The price of the essay on "Profitable Fruit Growing" is 1s. 3d. by post from this office.

Grapes Unsatisfactory (S. M.).—Though you took pains in packing the Grapes were shaken into a mass, evidently through the skin

being defective. The Vine has probably been overcropped, and is in a more or less debilitated state. Additional root action in fresh soil which contains lime and potash is requisite for the production of more substantial skins, without which the Grapes cannot keep long after they are ripe.

Shortening the Long Sappy Growths of Hybrid Perpetual Roses (An Inquirer).—You are quite right in shortening the long sappy growths of both standard and dwarf Roses to prevent their being broken by wind or snow. Shortening hard back, however, is not advisable, as if the spring prove mild growth will be made from the buds at the upper part of the wood retained, and is liable to be injured by spring frosts. Your practice, however, of pruning again in spring, merely shortening irregularities now, we find very desirable, particularly so in exposed situations.

Roses (S. S.).—Mr. Bardney does not paint the stems of his Roses with anything, and as he keeps them absolutely free from mildew by the method described last week he is satisfied, as anyone might well be, with Roses so clean, healthy, and floriferous as those in his charge. You can paint the stems of your plants if you wish. It will do no harm, and the sulphur will soon be washed off when syringing commences. The painting will not prevent mildew attacking the leaves under conditions that are favourable for its growth. No. 2 next week.

Jerusalem Artichokes (W. R. R.).—You say "The bulbs of Jerusalem Artichokes come all massed together in a lump at the roots of the stems; soil good light, and position frequently changed. Change of seed tubers has been recommended: can the want of this be the cause?" We print this question in case any of our correspondents can suggest a better method than the one indicated for overcoming the habit complained of. Wood ashes are excellent for the crop, but we can give no assurance that they would effect the desired purpose, and fresh tubers are worth trying.

Celery Running to Seed (J. H.).—The chief cause is too early sowing with checks to growth afterwards. To have good Celery at this season the first fortnight of March is a suitable time to sow, the plants being pricked off outdoors in early May, up to which they should be kept well up to the light in a cool house or frame, and be planted out in well manured trenches early in June, keeping them supplied with water, and affording liquid manure occasionally. With this treatment you will have splendid heads. For an early supply the seed should be sown early in February, the seedlings pricked off and grown on in gentle heat, hardening them off so as to be able to plant out in well manured trenches during the first moist mild weather after the middle of May. During summer it must be well watered and supplied with liquid manure in order to have fine solid, crisp, well-flavoured heads in late summer.

Thinning Larch Plantation (J. E. H.).—The Larch will now be suitable for stakes and various useful purposes, and the first thinning should be effected as soon as practicable. The trees being planted so thickly, it will be necessary to cut away about one-fourth of the worst shaped and ill placed, or, if the trees are very vigorous and require more room for their healthy development, it may be necessary to thin out more freely, always bearing in mind that excessive thinnings are more injurious than beneficial; at the same time the thinning must be efficient, allowing top space for those that remain, so as to insure a sturdy growth. Where the trees have grown most they should be thinned most, and *vice versa*. At the next thinning, say in three years hence, the trees will be suitable for rails and general fencing purposes. Therefore it is not advisable to thin too severely at first, but whilst considering the ultimate good of the trees, keep in view the utility of the thinnings, as they may be of little use at first, but if left a little longer (without prejudice to those that would remain after thinning), their value would be considerably enhanced. Judgment must be exercised, removing in the first instance the most unsatisfactory in growth.

Poinsettias Flagging (Weybridge).—The bracts of Poinsettias are apt to flag either in a cut or uncut state soon after being transferred from a warm stove to much cooler quarters. They are more serviceable either for table, house, or conservatory decoration if not grown in a very high temperature, but in any case they ought to be slightly hardened off before they have to "rough it." Even this will not prevent flagging in all instances where the bracts are used out of water for dinner table decoration. They ought not to be left on the table or to the tender mercies of the indoor servants all night, but the gardener or responsible assistant should attend at the proper time and place all that are needed for future use in water. A warm, rather than a cool place, is most conducive to freshness of cut Poinsettias, and we have frequently been under the necessity of taking them back to the forcing houses for a few hours. Moderately hot water also is better than cold for restoring them quickly. When nothing will recover them properly the heads may yet be split up and used for fringing groups of flowers, and the base of small fine-foliaged plants set on the cloth. A few green Poinsettia leaves with the coloured bracts are very attractive when made good use in cloth decoration.

Plants for Cut Flowers Outdoors (Old Subscriber).—Dahlias should be sown in early March, in gentle heat, and when large enough to handle be potted singly, and grown on in gentle heat, hardening so as to be strong at the end of May for planting out. Zinnias and Asters should be sown in frames in gentle heat in early March for an early bloom.

and in early April for a late one, in a frame either with slight or without bottom heat. The first will need to be kept steadily growing, pricking off in pans or boxes when large enough, and hardening well off, plant out after the middle of May. The latter may also be pricked off and carefully attended to, the chief thing being to keep the plants sturdy and clean, and to plant out at the end of May or early June. The summer flowering Chrysanthemums should have the cuttings inserted now, striking in gentle heat, potting and growing them in a cool house, but one in which they will not suffer from frost and damp through the winter, and in cold frames or a cool house in spring, hardening well off so as to place out sturdy plants in late May or early June. They should be shifted into large pots in spring, and be stopped when about 6 inches high. Chrysanthemum coronarium varieties should be sown outdoors early in April, or if you require early flowers they may be sown in gentle heat in March. Sweet Sultans are much esteemed for cutting, and so also are Cornflowers.

Converting Vinery into Peach House (*Inquirer, Kent*).—

There is no apparent reason why you should not successfully turn your vinery into a Peach house, but we question if you will do wisely in cultivating trees in pots in preference to planting out permanently. It is only the most skilful cultivators, and who in addition are in a position to devote much time and labour to their cultivation, who succeed in annually gathering profitable crops from potted trees, and if our advice is to be taken you will not adopt that method of culture. Your house being of good height—viz., 14 feet at the back and 7 feet high at the front, is admirably adapted for the system of training the trees on cross trellises as proposed. In most instances where the plan is a partial failure it is owing to the lowness of the fronts of the houses, much limited head room causing a woody rather than fruitful growth. Tomatoes would succeed remarkably well on the back walls, and such would also suit Peaches and Nectarines admirably, as it is not often these have a chance to spread to their full extent. Tomatoes might be grown well on the cross trellises, and the back wall devoted to Peaches and Nectarines. Trees that ripened fruit during June and July would naturally shed their leaves rather early, and in any case you may safely utilise the house for storing and flowering large quantities of Chrysanthemums. The latter thrive best in a dry airy house, only sufficient fire heat being employed to exclude damp and frosts. This would not unduly excite the Peach buds or injure the trees in any way, but many of the former might drop prematurely if any attempt to force Chrysanthemums were made.

Cinnamon (*L. M. S.*).—Cinnamon, which is the inner bark of *Cinnamomum zeylanicum*, a tree 20 to 30 feet high, and 12 to 18 inches in diameter. It is a native of Ceylon, but is found over almost the whole of India, the islands of the eastern Archipelago, South America, and the West Indies, in all of which it is cultivated. The whole plant has the same aromatic properties as is found in the bark of commerce. The root has the odour of saffron, and yields a great deal of camphor by distillation with sea water. The flowers have the smell and taste of the bark, and they furnish both an essential and concrete oil, which is used in the countries where it is obtained against dysentery, fractures, and as a cosmetic. The fruit has a smell somewhat like turpentine, and a taste like juniper berries; it is about the size of a Plum, of an oblong form and black colour. When ripe a fatty substance is obtained from it, called Cinnamon suet or Cinnamon wax, by bruising and then boiling it in water, and removing the oily substance which floats on the surface, and allowing it to cool and become concrete; this is used for making candles, which yield a most delicious odour. The wood has the same smell as the fruit, and is used for making trunks, boxes, and articles of furniture. From the leaves an oil is obtained, which more resembles that of cloves than of cinnamon, and which is sold by traders as oil of cloves. Cinnamon branches are seldom cut less than half an inch, or more than 2 or 3 inches in diameter. The bark is removed by making longitudinal incisions, and it is then taken off in strips. The strips are placed one above another, in parcels 8 or 10 inches thick, and allowed to remain for twenty-four hours, when a fermentation takes place, which facilitates the removal of the outer pellicle and the green part of the bark. The inner bark is thus left free, and is finally rolled longitudinally into cylinders or long quills, about 3 feet long, and the smaller quills are pushed within the larger; these are dried on clay, first in the shade and subsequently in the sun. When packed black pepper is used to fill the intermediate space, by which it is said that damp is absorbed, and the flavour of the cinnamon preserved.

Wire Structure for Fruit (*Northumbrian*).—Gooseberry houses or permanent structures covered with galvanised wire netting are frequently to be met with in various parts of the country, and in all probability their numbers will increase considerably. They are not devoted exclusively to Gooseberry culture, but are attached to high walls, these being furnished with Plum and late Cherry trees, while bushes of these and also Gooseberries and Currants share the covered space clear of the walls. In the midland and southern counties generally a south border would not be devoted to these fruits, a cooler aspect better suiting all of them. In your case probably a south border would suit any of the fruits named, and they might, therefore, be covered in permanently as you suggest, as well as the Peaches, Nectarines, and Apricots. The structure ought to be of a durable character, and so formed as to be uninjured by a great weight of snow, which lodges readily on the close mesh netting necessarily used. A gentle slope to the front is advisable for several reasons. The front

ought to be fully 5 feet high if bushes or dwarf trees are grown under the covering, and this in your case would give a fall of 4 feet from the back. It is advisable to use stout oak posts, the front plate being of good red deal. The rafters may well be 5½ inches by 2 inches, and if these are disposed 8 feet apart, duly morticed to the back wall plate, and fitted to the front plate, this will be all the framework necessary. In some instances the posts and rafters are placed 12 feet apart, and the latter further strengthened by having two purlins of 3½ inch by 2-inch deal. In order to keep out quite the smallest birds as well as mice, both of which are at times very troublesome, it is necessary to use ¾-inch mesh wire netting not merely along the front but over the whole structure. Larger sizes have been tried, but were not effective. It should be remembered that if birds generally are rigorously excluded from hardy fruit trees and bushes various insect pests, notably the Gooseberry caterpillar, may gain the upper hand, and prove more destructive than any other enemy. To counteract this evil it is a good plan to have a few large wire-covered shutters fitted in between the posts, these being removeable or fixed at will by means of stout hooks and staples. During the winter months or till such times as neither birds nor, as in your case, rabbits will be troublesome, the shutters may be kept closed, but just as the buds are bursting into full leaf the birds should be admitted, and not excluded again till the fruit is ripening. The wire netting would not afford protection from frosts, but with a permanent structure up it would be a simple matter to add mats or blinds. Glass being so very cheap, why not glaze the roof down to about 4 feet from the coping? This would necessitate occasional applications of water to the borders, but the great improvement in the quality and quantity of the crops would more than compensate. It should be added that it is a good plan to rough plane the timber used in the construction of a wire netting-covered structure, this admitting of two or three dressings of black varnish being applied with great preservative benefit.

Names of Fruits.—The names and addresses of senders of fruit to be named must in all cases be enclosed with the specimens, whether letters referring to the fruit are sent by post or not. The names are not necessarily required for publication, initials sufficing for that. Only six specimens can be named at once, and any beyond that number cannot be preserved. (*R. J. H.*).—The Pear is Easter Beurré. (*W. H. D.*).—Very good specimens of Golden Winter Pearmain. There has been no alteration in folding the pages, it is the customary way. Machine-cut pages usually spoil many numbers for binding purposes.

Names of Plants.—We only undertake to name species of plants, not varieties that have originated from seed and termed florists' flowers. Flowering specimens are necessary of flowering plants, and Fern fronds should bear spores. Specimens should arrive in a fresh state in firm boxes. Slightly damp moss, soft green grass or leaves form the best packing, dry wool the worst. Not more than six specimens can be named at once, and the numbers should be visible without untying the ligatures, it being often difficult to separate them when the paper is damp. (*W. M. A.*).—1, *Eranthemum pulchellum*; 2, Insufficient without flowers; 3, *Physalis Alkekengi*; 4, *Oncidium sarcodes*. (*W. C.*).—The specimens have been greatly damaged in transit, but as nearly as we can determine they are as follows:—1, *Adiantum assimile*; 2, *Adiantum scutum*; 3, Insufficient; 4, *Nephrolepis davallioides*; 5, *Adiantum pubescens*.

TRADE CATALOGUES RECEIVED.

J. Carter & Co., 237 and 238, High Holborn.—*Seed Catalogue (Illustrated with Coloured Plates)*, 1890.

H. & F. Sharpe, Wisbech.—*Seed Potatoes*, 1889-1890.

W. E. Bryce, Victoria Cottages, Archway Road, Highgate.—*Catalogue of Chrysanthemums*.

COVENT GARDEN MARKET.—DECEMBER 11TH.

No alteration.

SWINE.

OF an outbreak of swine fever at Sutton Marsh, near Spalding, the last report shows that the disease is still spreading. Fifty-eight diseased pigs have died, seventy-two more remain affected, and 105 healthy pigs have been slaughtered under the superintendence of the veterinary inspector. The average value of the pigs lost is about £3.

Norfolk markets are all closed against pigs, owing to the prevalence of swine fever. The County Council returns show that the number of affected animals during the last four weeks was 505, and so the pig trade is closed for an entire county just when prices are high and trade should be at its best. Well may it be asked, Why is this? The answer must be plain and clear. It is entirely owing to gross mismanagement and reckless carelessness. Not that we wish to point to the Prince's county as being singular in this respect, for it is notorious that cases of fever occur throughout the length and breadth of the land with lamentable frequency, simply because farmers will not have pigsties kept thoroughly clean. No doubt the disease is contagious, and the Lincolnshire Contagious Diseases Committee have done well to reimpose restrictions against pigs coming from Norfolk, Cambridgeshire, and the Isle of Ely. But it has its origin in filth and nothing else, and when a case can be proved to have so arisen on a farm we would make it penal. It is not an easy matter to obtain such proof, or indeed to get precise information how the contagion spreads. Within four years we have had two outbreaks, both at off-hand farms, which were so isolated and both in such open healthy situations that such a thing as swine fever ought never to have touched them. Close inquiry showed the pre-existence of the disease in the locality of each farm, and we have little if any doubt that it was taken to them by sows driven there for breeding purposes. Now, we had been at some pains and expense to obtain good boars of the middle white breed, and glad were we to allow neighbouring farmers to use

them, but we were eventually compelled to forbid the bringing of strange sows to the farms in self defence.

Faulty construction of buildings for pigs is frequently the primary cause of fever. Swine are filthy animals, and therefore due care must be taken to the certain evil results arising from a natural tendency to filth. Bearing this in mind, the floors of pigsties should be impervious to moisture, with a plain surface that can easily be kept clean. Our own home-farm piggeries have the floors of beds and open courts entirely faced with Portland cement, with a gutter running along the front into a drain at one end. These sties are used chiefly for sows and their litters. After the pigs are weaned, at the age of from six to eight weeks, they are either turned into a sty by themselves or into a separate compartment of an open lodge and yard. The sows' range of piggeries consists of an open court or pound, a roofed sty, with a passage behind from whence the sows may be inspected without disturbance. Each sty is sufficiently commodious to afford ample space for the sow and pigs. The governing principle is to use the sties entirely for sows and very young pigs, and keep all other pigs in open sheds with small yards in front of them. Filth is never allowed to accumulate in the sties, which have the floors frequently washed, and the walls are regularly washed with limewater.

The common fault of piggeries is paved floors, and courts half filled with filth. Another fault is the crowding of too many pigs together, and allowing them to lie down, or half bury themselves in filthy litter. They are naturally very sensitive to cold, and must have due provision of shelter and clean dry litter, to thrive as they ought to do. There is, in point of fact, urgent need of reform in the entire management of swine. A neighbour of ours has some old sows, huge unwieldly animals, which often run out to grass with the cows, but which we know full well are not suitable for breeding from, for they have become so large that the risk of sucking pigs being smothered or crushed by them is very great. It has long been a rule with us when sows become at all unwieldly, to fatten and sell them, however good they may have been for rearing pigs. All sows do not make good mothers, and two or three extra should always be kept, so that the requisite number of pigs may be maintained, and faulty sows be promptly got rid of. Let swine management be placed upon a sound commercial basis, and let there be an end of all careless, easy-going practice with them, as with all branches of agriculture. Good buildings, simple and cheap; careful feeding, thorough cleanliness, the best breeds, and careful cross-breeding, the prompt disposal of each animal as it becomes ripe for market or home use, or has ceased to answer its intended purpose in the best way. These are the lines upon which safe action may be taken, and then we shall cease to hear of closed markets and swine slaughtered prematurely.

WORK ON THE HOME FARM.

Wintering of live stock is now in full action, all cattle being settled in the yards till next spring, and no fitful running out on pasture on fine days will be allowed. It unsettles the cattle, and does more harm than good, for the scant herbage they crop is insufficient either to satisfy or nourish them. All calves not required for stock are now being fattened for sale as veal early in the new year, when they generally sell briskly and well. Surplus store cattle should be got rid of even at a sacrifice rather than run any risk of a want of home-grown food next March. The store of such food is more than usually abundant; silage, hay, straw, and roots are all here in ample quantities, and should be turned to better account than just feeding cattle that in the end afford no profit but the manure.

All Channel Island cows, and any others at all delicate or weak, are shut in the cowhouse at night, but strong healthy cows of other breeds have open lodges and comfortable yards. There is always much bullying among cows, and we take care not only to have ample lodge space, but to have brass knobs screwed upon the tips of the horns of quarrelsome animals. We have a friend in Suffolk keeping two large herds of cows who will have none but Red Polls, both because of their intrinsic excellence and that they have no horns. He is right for both reasons, and we can strongly recommend the Suffolk breed as first-class dairy and butchers' animals. Cows repay one now for a generous dietary as well as at any season of the year, so that it be wholesome, nourishing, and free of taint. But we never trust to "stale" cows in winter, however well and carefully they may be fed, but take especial care to have some to calve at intervals throughout winter. Down-calving cows are eagerly sought after during the next two months, and Dutch cows, though

yielding milk of inferior quality, are coming over every week in response to a brisk sale, caused by the fact of the cows having just calved, or being due to calve shortly. Prices in the sale yards near the landing stage range from £18 to £23, and the same cows are resold near the metropolis at an advance of from £5 to £10 per head. It is in this instance, as in so many others, that Mr. Middleman steps in and "bleeds the farmer." Alert, keen, and prompt, the middleman makes it his business to watch every market, to seize every chance. When will Mr. Farmer apply the lesson, and learn to help himself?

THE SMITHFIELD CLUB SHOW.

THE annual gathering in the Agricultural Hall, Islington, was opened on Monday last (December 9th), when the Prince of Wales and other notabilities attended to inspect the display. Cattle and sheep are well represented, but not quite so numerous as in some previous years. Pigs are about an average, and there is a remarkably fine show of implements, the galleries being filled, besides a considerable space on the ground floors. Upon the judging day considerable discussion was caused and much dissatisfaction expressed by several cattle entries being disqualified for non-compliance with age conditions. Some thus excluded had been prizewinners elsewhere, and it is said their registered ages can be readily substantiated.

Our readers are probably most concerned with the seedsmen's exhibits, of which there is the usual liberal display in the galleries. Messrs. J. Carter & Co., High Holborn, have an admirable stand well representing all their chief specialties arranged in a tasteful manner. A large portion of their stand is devoted to the exhibition of the Elephant Swede, all of which have been produced by customers in various districts of the country, including H.M. the Queen and H.R.H. the Prince of Wales. This Swede is of fine texture, rapid maturity, and hardy. A large practical farmer in Bedfordshire tested the hardness of the Elephant Swede by leaving it upon the land during the prevalence of some very severe frosts in the winter of 1887, and he reported that "it is as hard as iron." Some of the largest shown weigh 30 lbs. Examples of Warden Prize Yellow Globe, Mammoth Prize Long Red, Improved Golden Tankard, and Golden Intermediate Mangold, Prizewinner Swede, Champion Green-top and Purple-top Hybrid Turnip, Imperial Kohl Rabi, Thousand-headed Kale, and numerous other types of agricultural produce are also shown.

Messrs. E. Webb & Sons, Wordsley, Stourbridge, well maintain their reputation by an extensive and handsome stand of farm roots in all their selected and well-proved varieties. Fine clean well-developed samples are arranged in great mounds that have a most imposing appearance. Potatoes, Cabbages, Grass seeds, cereals, and numerous other specialties are well shown.

Messrs. Sutton & Sons, Reading, have a magnificent exhibition in the north gallery, comprising great piles of handsome roots. Very noticeable is a new Mangold under the name of Crimson Tankard. It appears likely to commend itself to growers who prefer a red Mangold. The roots are handsome and free from coarseness. Berks Prize Yellow Globe Mangold, of which some wonderfully fine roots are shown, has been awarded the valuable prize open to all England and Wales (given by Messrs. Proctor & Ryland) for the best two acres of Mangold. The Judges reported the weight of the crop to be 53½ tons per acre. Specimens of Golden Tankard Yellow Flesh occupy a prominent place; the roots are handsome. Mammoth Long Red Mangold is shown to great advantage, broad shouldered roots very free from fangs, and of great weight. The old Sutton's Champion Swede is given a leading place, but one of the finest groups on the stand is formed with Crimson King Swede, a large tankard-shaped sort, selected several years ago. It is specially valuable for early feeding, as it matures quickly. The upper part of the root is dark purplish crimson, the flesh deep yellow.

Messrs. Oakshott & Millard, Reading, and Messrs. Harrison & Son, Leicester, also have most creditable exhibits of their leading varieties of roots and farm crops. Mr. W. Kerr of Dargavel has a large exhibit of Potatoes, and several other firms also contribute to the general display.

REPORT OF THE SEED HARVEST OF 1889.

THERE is an unprecedentedly large crop of Red Clover seed grown in England, which promises to be of excellent quality. The Continental crops are also reported to be very good, and we have seen many examples of fine purple seed offering at favourable prices. American reports are not so satisfactory, in many districts the grain is exceedingly small and wanting in colour. A report says:—"Crop presented a very promising appearance, and outlook favoured a good yield, but through continuous wet weather, with cold nights, the growth and development is retarded, and unless we have hot dry weather the late seed will prove a failure." The Canadian reports say:—"Crop is very short, the midge having taken it off again."

The crop of White Clover in all producing districts is a very fine one; samples are bright in colour and of high germination, and moderate prices are expected to rule.

The output of Alsike both in Canada and Europe appears unsatisfactory. Canadian reports say:—"The seed is smaller and inferior to last season." It is therefore to be expected that the best values and best quantities of this article will be obtainable in Europe.

There is a good crop of Trefoil, both in quality and quantity. Present prices are ranging very low, as compared with the value of this article at the end of the sowing season last spring. Lucerne is a good

crop, and values are expected to range somewhat in accordance with last year's quotations. Reports of the Timothy crops are favourable, the area under cultivation has been very considerable, and the seed harvested in excellent condition. The crops of Rye Grasses have been harvested in magnificent quality; samples are particularly heavy, bright, and free from impurities, of high germination, and are offered at remarkably low prices at the present time.

Anthoxanthum odoratum.—Average crop, with good standard of germination. *Agrostis stolonifera* is scarcer than last year, and as so many samples are infected with ergot, pure parcels realise good values. *Alopecurus pratensis* is a good crop, seed bright and heavy, and of high germination, values expected to range moderate. *Cynosurus cristatus* is an average crop, both in Great Britain and the Continent; values may be expected to range rather lower than last year. *Dactylis glomerata*.—For this article the European market depends almost entirely on that of New Zealand. At the present time large quantities of seed are carried over from last year, hence low values are expected to rule. *Festuca duriuscula* is again a good crop of heavy seed and high germination. *Festuca pratensis* is reported much shorter than last year, and higher prices are being asked. *Festuca elatior* is a good average crop in Europe, and is quoted at a lower price than previous years. *Poa trivialis* and *nemoralis* are good average crops, bright heavy seed of high germination. *Poa pratensis* is shorter than usual, although samples are of fine colour and excellent germination. This seed may be expected to be somewhat higher in value than last year. Uncertain weather during harvest has materially damaged the prospects of many crops that promised very favourably at an early period.

Peas generally are scarcer this year than last. The English crop is extremely short, and American and New Zealand advices are of a similar character. Broad Beans are a full crop, but good bright level samples are not plentiful; Runner Beans, notwithstanding the mild autumn, do not promise to be above the average. The Onion crop is practically a failure both in England and on the Continent.

The Mangold Wurtzel crop promises to be more satisfactory; the seed has matured earlier than last year, but there is still a quantity in the fields, considerably damaged by late heavy rains. The production of Rape has been smaller than usual, and stocks are very low, whilst prices above the average continue to rule. White Mustard is a fair average crop, but there is little new seed offering, and the prospects of the English crop are not good; values are expected to be firm. Swede and Turnip crops were again harvested in excellent condition, and present values are lower than they have been for many years.

Cabbage seed will prove a short crop, and the Carrot seed crop will come out short, the wet weather that has attended the ripening of the seed being very destructive.

Potato crops, notwithstanding the ravages of disease amongst certain sorts in some districts, promises to be a very good one generally, and moderate prices may be expected to rule for a considerable time.—JAMES CARTER & Co.

AUSTRALASIAN AGRICULTURE.—In the introductory lecture to the agricultural class at the University of Edinburgh, delivered at the opening of the present session, Prof. Wallace chose as his subject some aspects of Australasian agriculture. In this lecture, which has now been printed, Prof. Wallace urges that sheep farmers in this country will shortly feel the effects of rivalry with the flockmasters of Australia. There are 100,000,000 sheep in Australia, mostly merinoes, which are not, by the way, a flesh-yielding but a wool-giving race. Prof. Wallace hazards the opinion, by a very easy process of arithmetic, that, before many years have passed, Australia will be possessed of over 200,000,000. He makes, also, the astonishing statement that merino mutton is equal in flavour and texture to our best Highland, Welsh, or South Down mutton. Upon these two assumptions, for they are nothing more, he foretells calamities to meat producers of this country, which he, it is to be hoped, will not live to see.—(Nature.)

METEOROLOGICAL OBSERVATIONS.

CAMDEN SQUARE, LONDON.

REMARKS.

- 1st.—Cloudy and cold.
 - 2nd.—Cloudy and cold, and slightly foggy in the morning.
 - 3rd.—Fine and bright throughout.
 - 4th.—Fine with the sun shining through clouds in the morning; cloudy afternoon.
 - 5th.—Cloudy, with showers turning to rain, and dull and drizzly all day.
 - 6th.—Cloudy throughout.
 - 7th.—Snow on ground in early morning, and it continued to fall slightly until noon.
- A cold week, the mean temperature being 32°; no intense frost, but very low maxima, the highest being only 38.1°.—G. J. SYMONS.

NOTES AND COMMENTS. EMIGRATION.

FROM time to time letters reach me, and accumulate, on a variety of subjects, and though they are attended to and briefly answered either publicly or privately, as each case demands, some of them are too suggestive to be cast aside, notably, I think, one from a traveller in search of what he did not find. This letter is dated Charlotte Town, Prince Edward's Island, Canada, November 5th, 1889, and may prove interesting to gardeners and others who may be contemplating a fortune-hunting trip to California. The letter was written after a sojourn of several months in the State referred to by a gentleman whose sound judgment, diligence, and skill as a physician enabled him to win a good position in the keen competition of London and to acquire means that justified him in leaving the Old World for the New in the hope of indulging in the pursuit which he loved of "growing something" better than he could grow at home; and his whole past life of enterprise on land and sea is a guarantee that he would not yield to trifling obstacles, hence the experience he relates is the more significant. Here is the Doctor's letter.

"I have not been able to write before as, being thoroughly disappointed with the barren desert of California, so unhesitatingly 'lied up' by my informants, I have been engaged for some months trying to find a place where I could cultivate a few vegetables, flowers, &c. As there is not an accessible acre of land on the American Pacific coast for which I would give five cents an acre, I have yielded to the entreaties of my family, and am on my way back to England, and shall call on you before Christmas. We have had a most wretched experience, and I am just recovering from fever and ague, caught in the Sacramento Valley, the people consoling me by saying that everyone has it; but I shall give you a true and unvarnished account of the whole country when I see you, and which I venture to hope you will be kind enough to insert in the Journal, with the view of deterring any more Englishmen ruining themselves and enriching the railroads by going to a country where nothing will grow except under from four to eight hours a day artificial irrigation. There is not a blade of grass in the State growing naturally, no hay therefore; abominable meat, no vegetables worth eating, and a temperature in the Valley of 115° during the day, falling to 54° and 58° at night. I have written down a few facts which I have seen myself, and had verified by old timer Californians, Texans, &c., and which are all literally true. All of us are now well. This climate (Prince Edward's Island) is grand; the fresh sea air mixed with the smell of the Fir and Pine trees is life-giving and most exhilarating. Charlotte Town is progressing not very rapidly, but surely. The farmers are, however, rapidly improving their farms, drive handsome traps, have good horses, and most of them roomy new houses and barns, and Mrs. B. says the country reminds her of England. The Island has always been called the Garden of Canada. It will do my heart good to see the old English faces and friends."

As is apparent, the home-sick M.D. very decidedly prefers the Canadian town, in which he regained health, to the dry and thirsty land in California, to which he seems to have been allured, and in which, instead of finding the flowers and fruits he longed for, caught the fever. California is a vast territory, and some parts are probably more favourable for emigrants to settle in than others. Fruit, notably Peaches, are grown in the open, the same as Apples and Pears are grown in England. There are also extensive Plum orchards, the fruit being chiefly dried and sold as prunes, while Grapes are produced on a large scale for wine-making purposes. That there is land worth much more than "five cents an acre" is undoubted, but my exploring correspondent failed to find it, though

others have succeeded. During the past summer Mr. Leonard Coates, who is engaged in growing fruit in California, spent several weeks in England, and I had the pleasure of conversing with him on the work in which he is extensively engaged; and if he did not find it profitable he would scarcely have been so anxious to return, seeing he has a good home in England, his father being the mayor of a provincial town. My correspondent, however, as I have said, evidently prefers the Canadian district from which he wrote, but the "old country" to either, the shores of which he is probably now approaching.

The experience of the gentlemen mentioned naturally leads to the important subject of emigration. From letters that reach me every week there is no doubt whatever, I am sorry to say, that the home market, to use a commercial term, is greatly overstocked with gardeners. Men of high character and unquestionable ability have been for a long time wearily waiting for appointments, and failing to find them at home, it is only natural they should direct their thoughts to the newer nationalities and more thinly populated territories beyond the seas. Men in ever increasing numbers are seeking advice on this most important subject, and as I am compelled to decline the responsibility of choosing for them a territory for a new home, I direct them to the best sources of information known to me. The first of these is the "Emigrants' Information Office," 31, Broadway, Westminster, S.W. This is referred to as follows in that mine of useful information, "Hazell's Annual for 1890:"—

"This office has been established under the supervision of the Colonial Office for the purpose of supplying intending emigrants with useful and trustworthy information respecting the British colonies. The classes chiefly required in the colonies at present are labourers and others connected with the land, female domestic servants, and farmers with a little capital. Hardly any assisted passages are now granted, Queensland, the Cape, and Natal giving the most encouragement. The importance of the subject is shown by the fact that the exodus from Great Britain has averaged during the last decade about 200,000 persons annually, of whom about three-fourths now go to the United States."

It may be added that the number of British and Irish emigrants in 1888 was nearly 280,000. Letters from persons desiring information and advice directed to the chief clerk at the address above given will be attended to without any cost to applicants. This is not a shipping office or agency established for obtaining passengers, but is a Government department, the officials gaining and disseminating the best information in the interests of persons who need it the most—intending emigrants. There is also a "Self-help Emigration Society" in London, established "for the underpaid and unemployed in Great Britain."

"This Society assists applicants whose character and fitness are assured to emigrate to Canada. The Society supplements the funds of the intending emigrant, and assists him to obtain his passage. Introductions are furnished to the Society's correspondents, who are men of position, forty-one in number, resident in various centres of Canada, and work is provided for the emigrant on his arrival out. The cost to the Society averages £2 10s. per head, and during the past year some 900 persons have been thus located at a cost of about £4500, £3000 of which was contributed by the emigrants and their friends. Employment was found for all who were willing to work. Application from intending emigrants should be made to Rev. R. Mackay, Secretary, 50, Fleet Lane, Farringdon Street, E.C."

I have no reason to doubt the genuine nature of this Society and mention it because I have of late received letters from persons whose capital is not sufficient, in my opinion, to justify their going on a prospecting expedition across the Atlantic. Too many have done this, and their small and hardly earned savings have been soon exhausted, and they have found themselves friendless, longing to return home, but without the means of doing so. It appears to me highly desirable that before leaving the Old World for the New, men with little or no capital should have introductions to residents there, whose willingness to aid them in obtaining employment has

been ascertained. Under those circumstances, thrifty able willing workers have obtained good appointments and positions; but, on the other hand, not a few who have made the venture without such provision have found themselves like lost sheep in a wilderness, and have had to endure privations which they never anticipated, and which would not have been exceeded, if equalled, at home.

In respect to skilled gardeners who have served private families and desire similar appointments abroad which they cannot find at home, one of them asked of me this question, "What do you think my chance would be if I went to America?" My reply was, "Ask a nurseryman of repute who knows you to give you a recommendation to write to a transatlantic firm of good standing which he may obligingly name; write to the firm, enclosing copies of testimonials, stating also your age and desire, and await a reply." Employment has been obtained in that way at once, and eventually good positions secured. I once asked a widely known American horticulturist to give me an idea of the demand for British gardeners in his "great country." His reply was significant. "Well, you know," he said, "you have plenty of men we don't want; they may be good gardeners and good workers, but insufficiently educated. We are ahead of you in that. Thoroughly competent, well trained, and well educated gardeners—in a word, workers, but gentlemen in speech and action, are the men we want, and there is a demand for such in America; but remember, we are overdone with mediocrities, and a man has small chance of getting a good place with us who cannot write a good letter." I do not comment on those remarks at present, but think it better to leave them for the reflection of those to whom they may be of interest. They are too serious to be disregarded.—J. WRIGHT.

JOTTINGS.

THE publication of a voluminous part of the Royal Horticultural Society's Journal reminds us that the exceedingly full and varied programme placed before the Fellows early in the year has been carried out in a manner which must be regarded as creditable to all concerned in the management. The outline of next year's proceedings has also been issued, and presents many features of interest, quite sufficient to ensure Fellows a substantial return for their subscriptions. The energy and enterprise of the Secretary, the Rev. W. Wilks, is evident in every department, and the increased popularity of the Society is undoubtedly largely due to his efforts. It is perhaps a long time since a secretary of the Royal Horticultural Society has adopted so broad a policy, and he wisely sees the desirability of recognising in a generous manner the existence and work of special societies. He was present at the annual meeting of the National Rose Society, of which he is a member, as he also is of the National Chrysanthemum Society, and he is announced as likely to be one of the visitors and speakers at the last-named Society's annual dinner on Thursday. Nothing will strengthen the Royal Horticultural Society so much as a pacific policy and friendly recognition of kindred organisations that are sharing in the work and doing it well. Virulent antagonism is profitable neither to societies nor individuals, but quite the reverse in the end, as the sympathies of all reasonable men are alienated by persistent, unfounded, or jealous opposition. It would be well if some hypercritical individuals would consider this in their own interest, for a man who assumes to be a universal critic is not only a public pest, but he commonly defeats his object. Generous, friendly criticism is most desirable for the common good, but a system of endeavouring to crush every project that does not emanate from a particular source can result only from exceedingly narrow views, an envious disposition, or private enmity.

The series of shows to be held during 1890 at the Royal Aquarium under the superintendence of Mr. W. Holmes has given rise to some discussion, and questions have been repeatedly asked respecting their connection with the National Chrysanthemum Society, and their material effects on the R.H.S. I can answer one of these questions positively—namely, that the National Society has no official connection with the shows which have been projected by the directors of the Royal Aquarium, who are providing the funds. The National shows in January, September, and November will of course form part of the series, and at the October show prizes will be offered for Chrysanthemums; beyond this the N.C.S. will neither gain nor lose by their success or failure. For my own

part I think it probable that if the dates of the R.H.S. meetings and Aquarium shows are conveniently arranged that both are likely to profit by the scheme. The two places are so near together that exhibits can be removed from one to the other in a short time and at a trivial cost, and if an exhibitor at the R.H.S. can see a prospect of recovering a portion of his expenses at the Aquarium he will not be slow to take advantage of it. The R.H.S. have adopted a consistent policy of offering no money prizes at any meeting or show. They have no doubt carefully considered the matter, and it is probably a right decision, as their funds will not admit of a lavish expenditure in prize money, and rightly applied they can be rendered more beneficial to horticulture in other ways. This leaves the shows practically to the nurserymen and such few amateurs as are willing to incur the cost of sending plants or other exhibits from a long distance. If only a portion of expenses could be paid it would greatly increase the number of amateur exhibitors, for after all we cannot ignore the £ s. d. side of the question in horticulture or in other trades. It is true that amateurs are often impelled by their enthusiasm to do even more than a tradesman, who simply regards the matter commercially, but it is more in the way of personal exertion and work, and few amateurs in these times are prepared to dip very deeply into their pockets in providing exhibitions for the advantage of others.

An impression seems to prevail that competitors at exhibitions gain enormous returns, and after a few years are literally rolling in wealth. This may have been correct at one time, when large money prizes were offered and there were a few exhibitors who enjoyed a monopoly at the leading shows throughout the kingdom, but it is not so now. Some specialists no doubt secure fairly good returns, but the utmost the average exhibitor can expect is to clear expenses. Any man who places the results of his skill before the public, whether he be amateur or gardener, may fairly require to see a prospect of recovering his outlay.

Some have said, Does the National Chrysanthemum Society intend to develop into a larger and more general organisation? If there were the need no doubt it could and would, but if the R.H.S. maintains and strengthens its position, such a course would be unwise and unsafe. An Orchid Society has been talked about, and substantial pecuniary support promised; but if the Orchid Committee of the R.H.S. is well and impartially organised, and performs its work satisfactorily, there will scarcely be room for a special society, as it might divide the interest, and a want of general support would be fatal to entire success. If the Committee had not been formed it is probable such a Society would have come into existence, and the R.H.S. might have even gained from the support of a strong young ally, in the same way as it could from the National Rose and Chrysanthemum Societies.

Several handsome Anthuriums have been shown from the Burford Lodge collection, and that named *A. burfordense*, exhibited at the recent meeting in the Drill Hall, was a worthy companion for those previously honoured. It had large rich scarlet shining spathes, broad and rounded, supported on stout stems well above the bold foliage. Quite a large group of Anthurium varieties and hybrids of this class can now be formed, and their decorative value is considerable.—L. CASTLE.

FRUIT CULTURE ON HEAVY LAND.

THE time has arrived for planting fruit trees, and as many readers may be engaged in this interesting operation for the first time, a few practical hints on the subject may be useful. It is very easy to dig a hole and bury the roots of a tree, but those who wish for immediate success must exercise forethought, consult practical experience, and if dealing with a heavy cold clay make some preliminary preparation, which may involve unthought-of expense. Better, however, plant fifty trees well than 500 badly. The former must bring profit and pleasure, the latter loss and disappointment.

It is not necessary to plant a tenth part of the varieties offered for sale; at the same time we believe there are few varieties in commerce but what may be profitably grown providing their peculiarities are studied and provided for. A variety, for instance, known to be a free strong grower at the expense of fruit should be planted in a shallow quick-draining border, containing a calcareous soil, not too rich—in fact, there are in plants as well as in animals constitutional peculiarities, which will often pay for finding out and providing for. In Nature it seems to be a rule, with very few exceptions, that the best thing requires the greatest amount of skill to produce it.

The advice so often given to keep the branches and shoots well thinned out is good, but we must not forget that the wood will not ripen if the roots are working at a great depth in a cold clay; there-

fore in planting endeavour to provide for keeping the roots near the surface, where they will feel the warmth of the sun—then, other things being equal, the wood and buds are sure to ripen, and fruit will follow.

To be successful in the cultivation of choice fruit on heavy clay soil we must have the roots completely under control, and provision must be made for preventing the border from become waterlogged, even through the wettest seasons. The mechanical conditions of a fruit border, whether indoors or out, is of the greatest importance, for if we can get a border thoroughly permeated with healthy fibrous roots the necessary chemicals can be easily supplied, either by natural or artificial manures; indeed, there are hundreds of barren fruit trees—not because they are growing in a poor soil, but because its mechanical condition prevents the trees from making anything but strong fibreless roots, consequently only sappy unfruitful shoots are produced.

It is not always a gardener's fault that the fruit trees under his charge are unfruitful, for he is frequently debarred for want of means and material from making the thorough preparations that his experience has taught him are essential to success. Garden proprietors will sometimes build walls at a great expense, but if a gardener asks to have a narrow border enclosed, so as to have the roots of his trees completely under control, he is often considered overreaching or putting the proprietor to unnecessary expense; hence he is obliged to plant his trees under conditions that can only bring him partial success. It is far better to prevent growth that is not wanted than to have to resort to the baneful practice of cutting out a quantity of shoots every year to keep the trees within bounds. We are well aware that judicious root-pruning will do much towards checking wasteful growth and promoting fruitfulness, but as prevention is better than cure, fruit trees that have to submit to any formal training should only have a limited root-space. This would prevent strong useless growth and induce fruitfulness. A shallow well-drained border, with some means of keeping the roots in it, is simply imperative on a heavy cold clay for the successful cultivation of all choice fruit. It would be difficult to estimate the quantity and value of manure and manure water that is annually wasted about the roots of fruit trees, because they are completely beyond the reach of it. First-class fruit that will ripen even in dull seasons is not produced after this fashion. Cultivators of such fruit know where to find the roots of their trees. They are, therefore, rewarded for the rich top-dressing and liquid manure that they annually give them.—J. H. W., *Leicester*.

AURICULAS SIXTY YEARS AGO.

I HAVE been looking over the "Florists' Guide and Cultivators' Directory," containing Coloured Plates of the Choicest Flowers Cultivated by Florists, with their Descriptions and an Account of the Most Improved Methods of Culture," by Robert Sweet, F.L.S., published by James Ridgway, Piccadilly, 1827 to 1829. To me this old volume is of intense interest, as some beautiful and truthful coloured plates of the leading varieties of Auriculas, Tulips, Carnations and Picotees, Ranunculuses, and other flowers are given, a Mr. E. D. Smith the artist, the illustrations being so true to Nature, and the colours still so good; in fact, it is a happy reminder of old days and old favourites, and growers long since gone from us.

Sixteen leading varieties of Auriculas of those days are illustrated and botanically described. These are Page's Duchess of Oldenburgh; Taylor's Glory in those days and for long after regarded as a glorious white edge, and still in Mr. Charles Turner's catalogue at 5s.; Stretch's Alexander, black velvety body colours and fine green edge, and described as being figured from a plant in the collection of J. Goldham, Esq., a name remembered by many an old florist as a cultivator of Tulips, Auriculas, and other florists' flowers, a long number of years since; Page's Champion, then a very beautiful green-edged, grown for a long period of years, and I believe still in some collections. The Editor remarks of this flower: "Our drawing was made from a plant in the collection of Mr. W. Smith, at Willow Walk, Bermondsey, from a plant that gained the first prize at the Hammersmith Show in April last (1826)," and further states, "It is one of the first-rate flowers when well blown, and is entitled to a place in all collections, but it requires particular care to keep it in good health, as it is not so free of growth as some varieties." Hedges' Britannia, another grey-edged variety, is figured, and it is stated that in Mr. Hogg's catalogue of that period the price was 20s. per plant. In Mr. Cannell's catalogue for 1881 this variety is named at 2s. 6d. as Britannia (Edge). It should be Hedges, as we well remember the variety; and in Cannell's subsequent lists it appears as Britannia (Smith's), and it is called "Smith's" in Mr. Turner's catalogue. I presume that at some time or other Smith's name was adopted,

as in the book I am referring to it is stated that, "Our drawing was made in April last from a plant in the collection of Mr. W. Smith, Bermondsey," who seems to have been a celebrated grower.

Grimes' Privateer, grey edged, is figured from a plant growing in Mr. Davy's nursery in the King's Road, Chelsea, London. Mr. Davy was a well known nurseryman in those days, and many an "old hand" will remember the old Pelargonium Davyanum, which made a sensation in those days. Grimes' Privateer still appears in Mr. Turner's catalogue at 3s. 6d. each. Cockup's Eclipse was for a long number of years held in great estimation, a fine green edged, and it still finds a place in Mr. Turner's catalogue, but it should be known as Cockup's, not "Cocup." Pollet's Highland Boy was a popular flower, so also was Mare's Navarino, a flower in which the green edge was very prominent. Another illustration is that of an old white-edged flower, Wild's Black and Clear, very distinct in its markings and colours, and taken from a plant in Mr. Hogg's celebrated Paddington Green collection: Redman's Metropolitan, a shaded self or Alpine, fetching in those days 7s. 6d. each. Smith's Waterloo, a large, bold, green edged, was much esteemed then, the selling price being 15s. to 20s. per plant, but I think this variety has passed out of cultivation. Lawrie's Glory of Cheshunt was in those days a very fine variety, and described as such in Hogg's catalogue and priced at 15s. to 20s. each. Howe's Venus is figured and described as a shaded Alpine. Booth's Freedom, for many years a very fine variety, is also illustrated, and the selling price 20s. to 25s. a plant. It is not improbable that this old variety still exists in some collections. Lawrie's Hertfordshire Hero, another large green edged variety, is also figured. With two or three exceptions these varieties formed part of a large collection of all the leading varieties in cultivation, which were under my charge close upon fifty years since, and the following varieties that we grew then are still to be found in Turner's and Cannell's catalogues—namely, Waterhouse's Conqueror of Europe; Chapman's Maria and Sophia; Fletcher's Mary Ann and Ne Plus Ultra; Trail's Beauty, I think; Kenyon's Ringleader; Lee's Bright Venus; Taylor's Ploughboy; Heap's Smiling Beauty; Hepworth's True Briton; Litton's Imperator; Oliver's Lady Ann Wilbraham and Lovely Ann; Dickson's Prince Albert; Smith's General Bolivar; and last, but by no means least, old Summerscales' Catharina, raised near Halifax in Yorkshire. I think we grew all these in our collection, at all events their names are very familiar to me, but I am trusting entirely to memory, as I have no notes by me of so far back.

We grew Auriculas then in span-roof pits, the brickwork about 2 feet high, and filled nearly to the top with rough ashes, one side of the span with glass lights, the other with shutters; the latter on the north side in winter, and used for shading on the south side in the spring and summer, plenty of air generally, and not grown in too large pots, and potted firmly. The soil, good loam, decayed cowdung, a little leaf soil and some sand. No cod-dling, but just good attention in watering, ventilation, and the removal of any decaying leaves or growths. Mr. Sweet, the author of "The Florist's Guide and Cultivator's Directory," I have before referred to, writing in 1827 to 1829, gives the following instructions as to culture:—"We think there can be no doubt but a mixture of nearly one-half of fresh light loam, chopped up small, and mixed with fine white sand and rotten dung in equal proportions, would answer just as well as all the compositions recommended (by others). The dung we would advise to be spread out then to sweeten it with the air, to keep the soil light, so that the roots may find their way through it with ease. Another thing of consequence to the health of the plants is to have the pots well drained, that the water may pass away readily."

In another old book, "Maddock's Florists' Directory," by James Maddock, florist, an edition published in 1822, edited by Samuel Curtis, the following compost for Auriculas is recommended:—"One-half rotten dung two years old, one-sixth fresh sound earth of an open texture, one-eighth earth of rotten leaves, one-twelfth coarse or river sand, one-twenty-fourth peaty or mossy earth, one-twenty-fourth ashes of burnt vegetables;" and the author goes on to render this complicated arrangement of soil more complicated still by various other instructions, which in these days would frighten many a beginner.—W. D.

YELLOW TOMATOES.

VARIETIES of Tomatoes that produce yellow fruits do not as yet appear to have gained much ground in the estimation of the Tomato loving section of our countrymen, but unless I am much mistaken the prejudice against them is in a fair way to be dispelled. For many years Carter's Greengage and the Large Yellow were the only two. The former with me has always proved somewhat too robust and shy bearing under glass, but it succeeds better in the

open, and no fault could be found with the quality, nor are there any yet to supersede in that respect. It is admirably adapted for dessert purposes or eating uncooked just when ripe and fresh from the plant, but its size otherwise militates against it, especially when offered for sale. Connoisseurs are of opinion that it is the most pleasingly flavoured of all Tomatoes, and it may be they are right. Of the Large Yellow very little need be said. The only time I had it true to name was when seeds were had direct from America. It yielded very heavy crops in the open air, the fruit varying considerably in form, some being ill-shaped, others presentable, while all were of a clear orange yellow, and the worst in point of flavour of any variety of Tomato yet tried. Sutton's Golden Nugget was the next noteworthy addition to the list of yellow fruited varieties, and this, again, proves much more fruitful against an open sunny wall than under glass. Each strong dis-budded stem is capable of perfecting four or five large racemes of fruit during a favourable season, these being small, oval-shaped, and of a deep yellow colour. Unfortunately the quality is not first-rate, otherwise it would be admirably adapted for dessert purposes. Given the flavour of Greengage, or even of Perfection, and it would be a model dessert variety.

Carter's Blenheim Orange or Apricot was the next in the yellow fruited section I had an opportunity of trying, and on the whole it is an advance in the right direction. It is of moderately strong growth, sets freely under glass or in the open, the fruit varying considerably in form, some being round and smooth, and others corrugated somewhat after the style of Large Yellow. The fruit are very clear skinned, the colour being a bright yellow with a tinge of crimson on the upper surface, this giving the fruit a very attractive appearance, a well selected dish, or such as was shown at the Chiswick Vegetable Conference, being very handsome. If eaten directly the fruits are ripe the flavour is brisk and good, or equal to most of the red varieties, and that is saying a good deal for a yellow Tomato. No Tomato is improved by being kept till it is over-ripe, but the yellow varieties appear to lose what little acidity they possess the most quickly.

During the past season we had an opportunity of testing three other yellow fruited varieties in addition to those already named, each being perfectly distinct and more or less valuable. Daniel's Golden Eagle belongs to the small round-fruited section, the fruit being produced in great clusters, and of the size and form of an Orleans Plum. It grows strongly, fruits freely under glass and in the open, the colour being orange yellow, while the quality is fairly satisfactory, especially when the fruit is grown under glass. Yellow King was grown against a sunny open wall. In everything but its colour and quality it much resembles the Mikado, being of robust yet fruitful habit, the leaves being large and broad, while the fruit is borne in large branching clusters, and attains a great size. In common with the Mikado the fruit varies in form, some being large and ugly, and others smooth, round, of great depth, and of a clear canary yellow. It is, however, a little flat in flavour. From New York comes the finest if not quite the best flavoured of all the yellow varieties. Henderson's Golden Sunrise might be briefly described as being a yellow Perfection, and from an exhibitor's point of view it is a great acquisition. With us it was of moderately strong growth, and against a sunny wall was exceptionally prolific. When growing, and before the fruit commences to colour, it might easily be mistaken for Perfection. When ripe very handsome dishes of large, smooth, round, clear yellow fruit were gathered, and which in a collection of varieties would tell well. There is room, however, for improvement in flavour, more acidity being wanted.—W. IGGULDEN.

NOTES ON SHRUBS.

IN making standards out of old Laurel hedges and other shrubs, I cannot lay stress enough on the importance of having the old bushes cut before Christmas, and rather in November, if convenient. The second season after I began some experiments I was sadly put out, and lost a whole season, as well as a dozen fine Portugal Laurels, by cutting them down to the ground in April, which is a good time for general pruning them, and, as I then thought, a good time to cut them close to the ground also; but it is not so. It is true the stools will shoot out profusely enough, but not so vigorously as to form clean stems the first year, without a constant pruning-in of the side branches through the growing season, and even then they would look knotty for a long time; whereas, by cutting them late in the autumn, strong succulent shoots will rise as straight as ramrods, and as smooth as a gun-barrel. I was also thwarted about the time of ringing the bottoms, to facilitate the emission of roots. Ringing must be done at, or a little after, midsummer; for, if you ring them any time in April or May, and cover the cut parts, a communication is soon formed by a new layer of bark. It was on a large stool of the Lilac, with thirteen strong suckers, and another of the common Privet, with nine suckers, that I first discovered that spring ringing has little influence in arresting the circulation, and I was rather

surprised at the fact; but so it was, and, as the whole went through my own hands, I could not be mistaken.

Standard Lilacs are very handsome when you can have them without the wilderness of suckers which they are so prone to send forth, and they are the easiest of all to make, except the snowball bearing Guelder Rose, which will make the most handsome of standards imaginable, and, in good soil, an old plant cut down will throw up suckers 7 or 8 feet high, with hardly a side branch. This and the common Lilac often throw up suckers, without the old plants being cut down, sufficiently long to make these standards, but unless they are well disbudded, and rings of bark cut out as above, you can never divest them of their natural way of producing suckers.

The common Syringa (*Philadelphus coronarius*) is another deciduous, rambling shrub, as prone to give forth suckers as the Lilac, but, treated as standards, they make beautiful little trees, and the troublesome habit of producing a host of suckers is got rid of. They make elegant little trees, like standard Roses, for forcing, in the spring. There are several others of this genus which ought to be in every shrubbery, whether as standards or huge bushes. These flower early in summer, and there is another species that does not flower till July, and on that account is valuable, besides that it is a very handsome shrub; the name is *Gordonianus*. In their natural way of growing these shrubs are little better than a Raspberry bush; indeed they are more trouble than ornamental that way, but train them into standards, and one could hardly believe how well they look.

I had a handsome round-headed standard of the old-fashioned Fly Honeysuckle in bloom last May, and two young gardeners mistook it for *Weigela rosea*. Now, of all the weedy things in the world, this Honeysuckle is the queen or king, when allowed to ramble about after its own fashion. Therefore, if handsome manageable plants can be formed out of such materials, surely it is better to have a good selection of them than to have grass plots and shrubberies stuffed with Laurels and half a dozen other common things.

The common Berberry makes a handsome standard, but how seldom is it tried that way, being only allowed to make a thicket of scrambling suckers—choking up the shrubbery like other plants of the same habit. Yet when reared up on a clean straight stem, 5 or 6 feet high, it forms a very interesting little tree, and while in fruit particularly so. There is another form of it called the Asiatic Berberry, which, if possible, is a still more interesting little tree, with bunches of purple berries in the autumn. This Berberry was distributed all over the country, and recommended for underwood in plantations, to shelter and feed game, for which use it is well adapted, and no poacher could force his way through a thicket of it, for it spreads from the roots as much as the common Blackthorn. There is one more Berberry called *B. aristata*, a brittle-leaved Berberry, which, I think, would answer well as a standard, though I have not seen it grown that way.

The *Kerria japonica*, with double yellow flowers, which may be seen in every old garden in the country, growing after the manner of the Raspberry, would make a singularly beautiful standard if the stem did not rise above 4 or 5 feet high. The long slender branches first grow perpendicularly, and then bend over gracefully, like plumes of feathers, and, when in full blossom, the weight of the flowers weigh down the branches till their points nearly sweep the ground.

The genus *Spiræa* furnishes a host of plants, which produce suckers in such numbers as to destroy each other. I never tried them, nor saw them tried by others, as low standards, but I am quite satisfied a great reformation could be made in their culture by getting rid of their suckers, and rearing them on single stems from 2 to 5 feet high, according to the growth. *Spiræa Lindleyana*, treated as a low standard, would form one of the handsomest plants that one could place on the grass, and when not in flower might be mistaken for a Sumach tree.

Speaking of Indian shrubs, where could you find a better subject for a handsome standard than the "*Beautiful Leycesteria*" of Dr. Wallich—a softwooded shrub, which caused a good deal of heartburning in this country a few years since, having not proved what it was at first reported to be, and is already almost neglected. It is also one of the "ne'er-dowells," if allowed its own way of growth, but elevate its handsome foliage, and its pendant clusters of flowers and fruit on a clean stem 6 feet high, and, my word for it, you will create a sensation in your neighbourhood. It has no English name, but commemorates that of William Leycester, formerly chief judge at the Bengal Presidency.

But enough; a book might be written on the subject, and not exhaust it. These examples are taken from the most common shrubbery plants—the most difficult subjects to deal with in any other way, and the least elegant in their modes of growth, when allowed to take their natural turn. Although I would strongly recommend this way of managing such plants, it is more for the purpose of getting rid of their propensity for throwing up a wilderness of suckers than for torturing their heads into globular forms, like those of standard Roses. Indeed, I would rather let them take their natural way of growth, merely preventing any large limbs or shoots being formed to derange the balance of their growth; and this is easily effected by stopping over-luxuriant growths occasionally, and by pruning the shoots in winter according to their size and strength—that is, the very short branches to be only a little shortened—the middle-sized ones to have one-half or two-thirds of their length cut off, and the small spray either cut out entirely, or cut into a few eyes, according to their position, and not allowing any to cross each other. This, of course, would be modified according to the way they produced their flowers after their head was properly set off. What would our Gooseberry and Currant hedges be if they were allowed their

natural way of growth? Their suckers would spring up as profusely as those of the Lilac, and their fruit would be comparatively useless. It is much the same with many of our ornamental shrubs; their flowers are in many cases only an apology for what they might be under a better system. We find no difficulty in informing our fruit bushes without suckers, and with clean straight stems, and we prune their heads in different ways accordingly as they best flower and fruit, and that is all that I claim for our ordinary shrubs, which, as at present seen, are living examples of our negligence and bad gardening.

Standard bushes were made with great industry by our ancestors, and the thing is as old as the hills, but in those days they pruned and clipped them into all kinds of fantastic shapes, which is altogether foreign to our present taste. All that is original in this plan is the certain way of getting rid of their contending suckers and side branches at once and for ever from the collar of the plant upward to the head. You may cut off the head ten years hence, and I shall engage for it that the whole stem will die back inch by inch, without the power of forming a single adventitious bud. Plants like the Lilac, which are naturally stoloniferous, that is, having the power of growing shoots from the main roots, would, no doubt, produce suckers from these roots under such a severe trial, but certainly not one from any part of the stem itself.—D.

AMERICAN BLACKBERRIES.

I CANNOT congratulate "De Nova," page 509, on the information he has tendered as to the great success of the American Blackberries; neither is the appendage to his note convincing. I was more deceived with American Blackberries than I have ever been with the many thousands of plants I have bought. Their price was no sham, neither was their trial here. I have no doubt you will publish any notes you may receive bearing on the question, but I have ceased to regard one swallow as making a summer. The persistent way they have been recommended, and the many years they have been before the public, warrant me, I think, in arriving at the conclusion that they are not generally satisfactory, but I am open to conviction.—SOUTH WALES.

[When our friend said on page 487 that he had travelled "almost from the Land's End to John o' Groat's and not met with a good crop," we ventured to suggest he might have travelled by an express train; if so, we think he went past some good crops of cultivated Blackberries that we have had the pleasure of inspecting.]

DENDROBIUM THYRSIFLORUM.

We have found evil consequences result by moving this *Dendrobium*, *chrysotoxum*, *densiflorum*, and others of a similar habit of growth, direct from heat to a cool structure. Their growths should be thoroughly ripened before any attempt is made to remove them from the structure in which they have made their growth. Plants that have growths not yet ripe should be kept in heat until they are thoroughly matured. Those that have reached this stage may be allowed to become dry at their roots and then removed to an intermediate temperature for a few weeks, and finally to a light position, where the night temperature will not fall below 50°. When moved direct from a warm to a cool house the roots frequently perish, and any growths not thoroughly firm damp off at the base, the foliage becomes blotched, and the plants are disfigured. This will also take place under any circumstance if the temperature in which they are placed is low. Even in a temperature of 60° cold draughts must be avoided, the atmosphere being rather dry, the plants given only sufficient water to keep their pseudo-bulbs fresh and plump.

ZYGOPETALUM MACKAYI.

The flower spikes are rather stiff, but they are nevertheless very suitable for large vases. Its flowers are highly fragrant, and as they are produced during the winter it is worth growing in quantity where choice flowers are in demand at that period of the year. We find it invaluable for decoration in the conservatory, where its flowers last fully double the length of time they will do in heat. This plant evidently enjoys the cooler treatment of the conservatory for a few weeks, provided it is carefully treated, and grows afterwards with increased vigour. While in this structure they should be arranged where cold draughts will not strike upon them and kept rather dry at their roots; in fact, little water will be needed, but when it is necessary it should not be of a lower temperature than 60°.

LYCASTE SKINNERI.

We are removing the whole of these to the coolest end of the *Odontoglossum* house, except a few plants that made their growth

early and are already showing flowers. These plants are often kept too dry during the season of rest, and the effect of such treatment is visible the following year by the plants decreasing in strength. Considerably less water is needed than during the season of growth, but we never allow the soil about their roots to become thoroughly dry. When in flower these plants can be used in the conservatory or even in dwelling rooms without the slightest injury. When used in the conservatory, it is necessary to elevate this plant well above surrounding objects, or the beauty of its flowers is hidden.

THUNIAS.

These should be sufficiently ripe for storing under the stage or placing on a shelf where they can be kept perfectly dry in a temperature of 45°. To do them well they enjoy a complete season of rest, and grow with great vigour afterwards. Plants that have been grown in a moist shady atmosphere will need considerable care to prevent their decay. It is not wise to place plants of this nature in too low a temperature, or they will be certain to suffer. They should be kept a little warmer and in a dry atmosphere. It is also necessary to examine them frequently.—ORCHID GROWER.

CYPRIPEDIUM NIOBE.

THIS hybrid was shown by Messrs. J. Veitch & Sons at the last meeting of the Royal Horticultural Society's Floral Committee (Dec.

FIG. 67.—CYPRIPEDIUM NIOBE.

10th), when a first-class certificate was awarded for it. The plant was obtained from a cross between *C. Fairrieanum* and *C. Spicerianum*, very interesting and distinct, showing at a glance the influence of the two parents. The dorsal sepal is much like that of *C. Spicerianum*, but somewhat more green at the base, veined with deep purple. The petals are undulated at the margin and strongly recurved, just like *C. Fairrieanum*, green, and a peculiar reddish brown tint. The lip is small, neat, and of a greenish hue.

CELOGYNE CRISTATA.

THOUGH this is one of the easiest of all Orchids to grow and flower, it does not always follow that everyone succeeds with it. I know a large number of plants in various places where flowers are produced in sparse numbers, and yet the plants appear to be in good health. The variety has a bearing on this point, as I find the common sort, which yields four or five blooms on a spike, by far the most floriferous, the longer spiked Chatsworth variety flowering much less profusely, and in the aggregate yielding a smaller number of blooms.

I began with a small plant a dozen years ago, each was shortly after divided into four, and the pieces encouraged to grow. The last time these were repotted was six or seven years ago, when the plants were spread out on elevated mounds in large pots, and since then they have only had the pseudo-bulbs thinned, and occasional dressings of fibrous peat or sphagnum applied. These plants grown quite close to the glass in an ordinary plant stove flower with great profusion. The larger of the four I estimate will this season yield 1200 blooms, which at the low average of 1d. each

means £5 as the produce of one plant, while, strange to say, the plant itself if put in the market would not fetch that price. When the spikes are expanded and the flowers open it does the plants no harm, but rather, I imagine, is to their benefit to keep them in a cool and dry structure, giving little or no water meantime. The flowers keep thus much longer in good condition, and the breaks, though later, come more evenly and in greater number than if kept on in the stove. Before returning to the stove the foliage and pseudo-bulbs are thoroughly washed, a white scale appearing in small numbers, and this is the period when cleansing can be pursued with the greatest success and with the least chance of damage to the plants. I have seen plants very much damaged by the minute Orchid thrips, but it is only where a very high temperature and a dry atmosphere is kept up that this destructive pest attempts to gain a footing, and as it is on the young growths that thrips congregate the damage they effect is of a very serious nature. Whenever they are seen, or rather the blackish appearance of the pseudo-bulbs and foliage which results from their attention, for the insects themselves are not easy of detection, the sponge must be brought into immediate and unremitting use.

The kind of soil this *Cœlogyne* appears to do best in is one of best fibrous peat, sphagnum, and sand, with free drainage. In potting it is best to give good shifts, and allow the plants to remain undisturbed for a few years, as my experience shows that they flower best when undisturbed at the roots. Our plants are freely watered from the time the growths are well started until the flowers are open, when the water pot is dispensed with for a month or two. I have tried plants in a cool house, but results have been so much inferior that all our stock is now grown in a stove temperature.—B.

THE CLYDE DISASTER.

I HAVE much pleasure in informing you that this fund amounts to £450, including the munificent donation of 20 guineas from G. N. Stevens, Esq., Tulse Hill; 3 guineas from Messrs. Hurst and Son; 1 guinea from Mr. A. Methven, gardener to Baroness A. Rothschild, Geneva, and other smaller sums. As we have another and final Committee meeting on Friday next, I cannot foreshadow either the distribution of the money or the thanks to the *Journal of Horticulture* for kind co-operation with us, but will give you full particulars next week.—FRED. HORSMAN, *Hon. Sec.*

BAMBOOS.

THE *Kew Bulletin* for December contains several interesting chapters, and amongst them is one comprising a report of a visit to the Riviera, and notes on the tropical and subtropical plants there seen. The remarks on Bamboos are here reproduced.

After the Palms the most tropical feature in the gardening of the Riviera is the Bamboos, which are largely used in the composition of the best gardens, both public and private. To a northern gardener the elegance and grandeur of some of these Bamboos constitute some of the chief charms of the Riviera. Some of the specimens are of very large dimensions, as for instance one of *B. vulgaris*, in Baron Vigier's garden at Nice, which measures 40 feet through in every direction, and is 35 feet high. It contains hundreds of stems or canes, each 3 inches in diameter, and straight and smooth as a gun barrel. It is planted on one side of the lawn near the house. As fences, screens, and boundary lines the Bamboos are frequently used, and nothing could be better, as they are quick growers and evergreen. All the kinds noted were in splendid health, and from the manner in which they had taken possession of the ground it was evident that their requirements are abundantly satisfied. The finest and healthiest examples are in wet ground, often on the edge of water. Most of them are heavily manured annually.

In England we have not hitherto made the most of this beautiful family of plants, many of which may be grown out of doors successfully in all the milder parts of the country, whilst in large conservatories, where they would get protection from cold in winter, a still greater number would be found to thrive. That they are much superior to many of the plants at present used for such positions must be evident to anyone acquainted with the extraordinary elegance and grace of a well-grown Bamboo.

The Kew collection comprises over fifty named sorts, a few of which are tropical, whilst the bulk of them are either quite hardy or require only the temperate conditions supplied by the winter garden.

The names of Bamboos are as confusing as are those of garden Palms. In one as in the other it is only very rarely that the plants flower under cultivation, so that many of the names which are given by nurserymen can only be problematical. For garden purposes this would not be of much consequence, the difficulty arising only when growers do not agree as to what names the plants shall bear.

Now that so many kinds of Bamboo are in cultivation under favoured conditions on the Riviera it would be worth while to watch them, and as they flower get them properly determined.

It is generally supposed that nearly every member of the Bamboo order perishes immediately after flowering. There are many recorded

instances of this having occurred. But with regard to a considerable number of the species the exact flowering age has not been ascertained. Some are said to grow forty years before flowering. Another remarkable fact is that all the plants of one generation flower at the same time, no matter how different may be the conditions in which they happen to be placed. I was told that all the plants of *Thamnocalamus Falconeri* (*Bambusa gracilis*) of the Riviera flowered and died last year. Numerous seedlings have since sprung up about the old stools, but the latter certainly all perished. This proved to be the case with a plant of *Arundinaria falcata*, which flowered at Kew in 1886.

The following are the kinds noted. The names in brackets are what I consider to be the correct names, according to Munro, &c.

B. aurea, Sieb.—A Japanese species, now well known in gardens. It was in cultivation at Kew in 1866, and is here still. It is one of the most elegant of the hardy Bamboos. In the gardens of the Acclimatization Society at Hyères there is a magnificent specimen with stems 25 feet high, and not more than 1½ inch in diameter. The nodes are prominent, and less than 4 inches apart on the lower part of the stem. When ripe the stems are of a rich greenish-yellow colour. The leaves are small, with a distinct petiole.

B. gigantea (*Dendrocalamus giganteus*, Munro).—The largest of all the Bamboos. The specimen at the Palm house at Kew produces stems 40 feet long and 12 inches in circumference, but wild plants have stems as much as 26 inches round. In the garden at Villa Valetta, Cannes, there is a very fine mass with stems 30 feet high and 4 inches in diameter. It is a native of India.

B. gracilis (*Thamnocalamus Falconeri*, Hook. f.).—A slender and somewhat fragile stemmed plant from the Himalayas. It is not uncommon in gardens, as it makes an elegant pot plant. It was plentiful on the Riviera last year, when all the plants flowered. There is a plant at Hyères called *B. gracilis rustica*, in which the leaves are narrow, with incurved margins.

B. Mazellii, Hort.—A fine mass at Hyères and Cannes. The stems are 25 feet high, bright yellow when mature, the nodes prominent and close together at the base, the branches loose, and the leaves short and twisted on the petiole. It looked suspiciously like *B. aurea*.

B. Metake (*Arundinaria japonica*, Sieb. & Zucc.).—Much used on the Riviera, where it is as ornamental as it usually is in England. It is always strongest when grown near water, although it grows well in an ordinary border. At Kew there is a specimen 12 feet high. According to Munro it is known as *B. mitis* in the gardens of Paris.

B. mitis, Poir.—A magnificent specimen on the lawn at Villa Valetta, the stems 30 feet high and 3 inches in diameter at the base, becoming shining yellow with age. The nodes are prominent, and about 9 inches apart; the leaves short and not dense. There is a small plant of it at Kew, obtained last year from Lavallée's collection. It is said to be from Cochin China.

B. nigra (*Phyllostachys nigra*, Munro).—A clump of this, 20 yards through, and rising to a height of 30 feet, in the garden of Baron Vigier at Nice, was one of the most striking objects seen on the Riviera; thousands of naked shining blackish purple stems rising from the lawns, and losing themselves in the mass of green foliage above. This species is quite hardy in England, but it does not grow to its full height except when in a very sheltered situation or under glass, as at Chatsworth, where in the large conservatory it is exceedingly handsome.

B. quadrangularis, Fenzl.—A very interesting species from China, with stems 15 feet high by 1 inch in diameter, and distinctly quadrangular; the nodes are armed with decurved teeth-like spines. These dimensions are of a clump 6 feet through on one of the lawns at Villa Valetta. There are plants at Kew, both outside and in the Temperate house. It is a handsome and distinct Bamboo. For an account of it see an article in *Nature*, vol. xxxii. (1885), p. 391.

B. Quilloi.—I cannot find any information with regard to this plant. Carrière described a Bamboo in the *Revue Horticole* under the name of *B. Duguilloi*, but Munro appears to have referred this to *Phyllostachys puberula*, included by him under *P. nigra*. The plant known under the above name is represented at Hyères by a large clump with stems 25 feet high, 1½ inch in diameter, bright yellow, with a faint tendency to become quadrangular. We have a plant of it at Kew. It is a most elegant Bamboo.

B. scriptoria, Hort. (*B. nana*, Roxb.).—I believe that *B. scriptoria* of the Riviera gardens is merely a form of the well-known Chinese *B. nana*. It has the same dense habit, thin green canes, and small leaves with the under side glaucous, which characterise *B. nana*. In some of the specimens seen the stems were 9 feet high. A variegated form called *B. scriptoris* is the same as is grown at Kew as *B. nana variegata*.

B. Simoni, Carr.—A beautiful Bamboo, and perfectly hardy in England, as is shown by the fine example in the Cambridge Botanic Garden, and by the plants at Kew. It is also very handsome at Hyères, where the canes are 15 feet high, quite smooth and cylindrical, less than an inch in diameter, and coloured deep olive green. This plant is worth the attention of English horticulturists on account of its elegance and hardiness, and its evergreen character.

B. sulphurea.—Apparently a garden name for a very handsome Bamboo, with stems 18 feet high, 1½ inch in diameter, the nodes 9 inches apart, and the internodes deeply furrowed on one side. When mature the stems are a rich orange yellow colour. There is a fine mass of it at Villa Valetta. It is also in the Kew collection.

B. verticillata.—This is probably the "Male Bamboo" (*Dendrocalamus strictus*, Nees), a common Indian species, the stems of which,

According to Munro, are universally used as lance-staves. The specimens seen were large clumps, the stems 20 feet high, 1 inch in diameter, the nodes at the base a foot apart, the upper ones bearing each a crowded cluster of short leaf branches. When old the stem is bright yellow. It is a well marked handsome Bamboo.

B. violascens, Carr.—A beautiful Chinese Bamboo, which was introduced into Jardin d'Acclimatation in 1870, in the branch of which at Hyères a fine clump was noted. The stems are 10 feet high, three-quarters inch in diameter, much branched towards the top, the internodes somewhat flattened on one side, and striped with violet on a greenish yellow ground. The leaves are glaucous on the under side. Young plants of it are in the Kew collection.

B. viridi-glaucescens, Hort.—One of the handsomest of cultivated Bamboos. It is quite hardy in England, and in France it is one of the commonest. It grows very rapidly, has handsome foliage, transplants easily, and a first-rate pot plant. It is frequently used in France for the embellishment of entrance halls, and is very effective. The stems of the Riviera plants were over 20 feet high, very slender, the nodes about a foot apart, dark green when young, bright yellow when mature.

B. vulgaris, Wendl. (B. Thouarsi).—Some astonishing large healthy specimens of this well-known species were met with. Apparently it does not require tropical treatment such as it usually gets. At Hyères, Cannes, and Nice it is especially fine; in the last named place measuring 40 feet through, and the canes 35 feet high. The plant in the Palm house at Kew must be thirty years old; it has not yet flowered.

THE STANDARD ROSE STOCK FOR THE FUTURE.

FOR a number of years the culture of Roses has been increasing to such an extent that nurserymen began to be at a loss whence to obtain stocks for dwarf Roses as well as for standards. The custom has become general to grow seedlings of *Rosa canina* as well as the Manetti, polyantha, and other kinds for this purpose; but with all these there are so many well known inconveniences that it would be most desirable to find a more suitable type for a stock. Everywhere nurserymen have been trying to procure such a species, and we also have been experimenting for upwards of ten years, choosing especially Central Asiatic kinds for the purpose of having a stock which would be perfectly hardy. The beautifully straight stems nearly without thorns of *Rosa laxa*, *Retz*, brought us to the idea that this species would answer our purpose. Our attention once fixed upon it, we soon found other qualities, which will put it above all competition for this special purpose.

While others are very troublesome through the numerous shoots arising directly from the roots, *Rosa laxa* never forms any suckers. The stems are not only perfectly straight and nearly without thorns, but they scarcely branch out at all, and, moreover, they are very hard and firm, containing very little pith; for this reason they will withstand any amount of frost and proved perfectly hardy without any protection even in the severe winters of 1870 and 1879 to 1880.

Another very important thing is the relatively short season of growth of *Rosa laxa*. While *Rosa canina* and its congeners keep growing late in autumn until frost forces them to rest, *Rosa laxa* will finish growing by the middle of September. In consequence the Roses budded on it rest in good time, and so to ripen their wood thoroughly, so they will resist frost much better and become far more hardy when budded on *R. laxa*. Roses forced to rest early in this way will of course be excellent for forcing purposes. Any kind of Roses takes easily when budded on *Rosa laxa*. They will join firmly, while for instance Roses budded on the Manetti will sometimes fall off again. We possess a variety of standard Roses as well as dwarf ones budded two and three years ago on *Rosa laxa* so as to be perfectly able to judge.

Growing standards of *Rosa laxa* is of the very easiest description. The plants are to be treated just like other nursery stock, but not to be cut back until the growth to be used for a stem is formed and has attained its height. We possess large pieces of land occupied by such standards of *Rosa laxa*, and to a grower of Roses it would be a pleasure to walk through them and to see the clean straight rows of standards. While such pieces of land planted with other stock Roses are hardly to be kept clean on account of the suckers and branches and rather look like wilderness than an orderly nursery piece, these are as clean quarters of the nurseries as any, and we can comfortably walk through the rows. All these are qualities which will put *Rosa laxa* above any other Rose for a stock. Besides, it is an ornamental shrub, resembling somewhat *Rosa pomifera*.—OTTO FROEBEL.

TEA ROSES FOR EARLY FLOWERING.

These have frequently large quantities of leaves at pruning time, and for years all healthy ones were preserved and allowed to fall naturally, which they do in a short time after the plants have started into growth. Frequently these old leaves are infested with red spider, aphides, or mildew, and remain upon the plants sufficiently long to give the culti-

vator some trouble. For the past two or three years we have removed the foliage during the operation of pruning, the house is also thoroughly fumigated two or three times in succession before the plants are started into growth. We have not observed any ill effects resulting by the removal of the leaves. It is a certain method of clearing out insects and the destruction of any spores of mildew that may still be upon them.

RENOVATING PLANTS IN POTS.

Where plants have been forced for some years and subjected to repotting annually, there is certain to be some that have failed to do satisfactorily. Whether these are Teas or H.P.'s the best method of restoring them again to health and vigour is to give them a season's rest—that is, allow them to come forward steadily and almost naturally in cold frames. Plants in this condition should be turned out of their pots and the old soil carefully picked from their roots. If the soil about them is not thoroughly sweet, the whole should be removed. Place the plants in much smaller pots, according to the size of the plants, in a compost of good loam, one-third leaf mould, one-seventh of manure, and a liberal quantity of sand. In reducing the roots all the fibres possible should be retained and the plants placed in cold frames. It is wise to plunge the pots to prevent evaporation, and thus avoid having to water them. The majority of the plants given this treatment and carefully watered during the early months of the year, will start strongly and grow vigorously afterwards. It is useless to shake them out and then force them into growth; it would ruin them. They will flower just before flowers can be had from those in outside borders, and will prove very acceptable at that season of the year. It will be necessary to repot them directly they have flowered, and therefore small pots in which to start them is strongly advised.—NORTHERNER.

MANNERS AND CUSTOMS—A CATALOGUE COMMENTARY.

(Continued from page 491.)

Annie Wood (Verdier, 1866).—Here we have a Rose with habits and manners (fortunately) peculiar to itself. A fine strong grower, with fair foliage, liable to mildew but not much injured by rain, and a very free bloomer. A great quantity of buds form on each stem; the top bud of all, which one would naturally reserve, is nearly always cracked, hollow, and distorted, before it is much bigger than a thimble, and sometimes has a great green pip in the centre. You may search for the best shaped bud all over the stem, and do away with all the others for its sake. Even then, nine out of ten buds will show a great eye before they are more than half expanded, and the tenth will do it soon after being cut. You make up your mind to discard the sort altogether; but, just at the close of the season a beautiful bloom makes its appearance on a shoot you had not noticed, with brilliant colour and good imbricated shape; and the plants are spared to serve you just the same trick another season.

The title of my paper being what it is, it seems impossible to avoid sooner or later lugging in the time-honoured anecdote of the traveller, who, describing the "manners and customs" of some native tribes he had been visiting, was constrained to dismiss one of them with the terse remark, "Manners none—customs disgusting." If it be possible to say anything so bad of a Rose, I am doubtful whether I shall find any more worthy candidate in the N.R.S. catalogue than *Annie Wood*.

I see that a Rose called "Professor Edward Regel," of which I know nothing, is stated to be "in the way of" *Annie Wood*. If it be too late for the Professor to mend his ways, I should strongly advise his friends to keep his unfortunate predisposition in the dark.

Baron de Bonstettin (Liabaud, 1871).—A stronger grower with good foliage, liable to mildew and to be injured by rain. Very early; one of the first to show flower buds. A poorly shaped flat bloom at the best, and but a small proportion of them come good, but a beautiful dark colour, being perhaps more "velvety" than any Rose. Requires a hot season, and yet very liable to "burn" in a bright sun. Is held by the N.R.S. to be identical with *Mons. Boncenne*. With me the Baron has seemed rather the better grower, but that may have been chance. Fairly free blooming, and fair size, but does not last well, and is not much use as an autumnal.

Baroness Rothschild (Pernet, 1867).—A Rose by itself, with very distinct manners, belonging to all its family, which is not large as yet. Of "robust" habit—i.e., with comparatively short, thick, stumpy, upright, stiff wood, and grand foliage right up to the blooms, which are generally produced singly; not liable to be much injured by mildew, red rust, or rain. The blooms generally come well, of what the N.R.S. calls the cupped shape; but I should have thought the perfect form was globular, and I have never had it of real cupped shape, like *Anna de Diesbach* or *Coupe d'Hébé*, without a very visible eye. One of the very best of autumnals, and of the fullest size, but quite scentless. A party of villagers came to see my Roses one day, and one good dame who was behind all the others stooped to catch the perfume of a fine bloom of the Baroness, which had attracted much notice. She was disappointed, but saw the reason at once. "Ah! they've sniffed all the scent out of this 'ere one!" Is rather wanting in fulness of centre, apt to open quickly in hot weather, and must be cut small for exhibition. It may be only fancy, but I have half suspected deterioration in this fine Rose of late years; it seems less fine and less lasting than it used to be. Is much inclined to sport to white. *Mabel Morrison* and *White Baroness* were comparative failures, but *Merville de Lyon* has achieved a great success. *Mabel Morrison* has, however, amply atoned for personal failure by its wonderful progeny, *Her Majesty*. I do not know whether *The Puritan*, a new Rose of 1887, too young to have its fortune told, but apparently of bad manners in the open, is also a white descendant,

but it looks something like it. Baroness Rothschild is likely to continue long in favour, even if it has slightly deteriorated, for it is of strong, hardy constitution, and does fairly well on its own roots.

Beauty of Waltham (W. Paul, 1862).—Only fair in growth and foliage, not particularly liable to mildew or to be injured by rain. The blooms seldom come falsely shaped, the form being typical. The N.R.S. catalogue calls it imbricated, and the raiser cupped; my blooms never come in either of these forms, but the petals are very closely curved inwards in the centre in a manner which proclaims the variety at once. Like some others somewhat of this shape, and those of the pointed form, this Rose has the good custom of closing in and guarding its centre more tightly in hot weather, when it is most needed, than at other times. I saw, by-the-by, the other day, a line of the Poet Laureate's misquoted in some paper (not this Journal, I should think), to read, "Tiptilted like the petal of a Rose." It should, I think, be "the petal of a 'flower.'" I never saw a Rose petal whose shape could in any way suggest a turned-up nose. A free bloomer, good in lasting qualities, and as an autumnal, but not of the largest size. Has produced a seedling, Lady Arthur Hill (Dickson, 1889), of novel colour.

Benoit Cmte (Schwartz, 1883).—See Alfred Colomb.

Black Prince (W. Paul, 1866).—Of fine growth and foliage, and occasionally gives quite a good dark bloom, but so very rarely that I am forced to look upon it more as a pretender than a Prince.

Boule de Neige (Lacharme, 1867).—A cross with the Noisette race, of good growth and fair foliage, not liable to mildew or much injured by rain. The flowers do not always come right, they should not be thinned, or the probability of distortion is increased. N.R.S. catalogue gives the shape as "open cupped," but with me they are imbricated, perfect rosettes in every sense. A lovely pure white charmingly shaped Rose, but it is an abuse of even catalogue-English to call it medium sized, as it is impossible to deny that it is very small. Exhibitors are sometimes accused of caring only for big Roses, but I am sure there are some who have wished that *Boule de Neige* was three times the size it is, and it would then be not too large, for we should certainly have nothing to equal it for show as a white H.P. Stout in petal, and lasting in bloom, very free flowering, and good as an autumnal.

Camille Bernardin (Gautreau, 1865).—Fine growth and foliage, but the wood is not very stiff, and the blooms are sometimes pendent. Decidedly liable to mildew, but will stand some rain. The majority of the blooms come well, and are good in size, petal, fulness, and shape. Not imbricated with me, but of pointed centre. Lasting and fragrant, a free bloomer, and a good autumnal. A Rose of good constitution, most useful and reliable for garden or show purposes.

Captain Christy (Lacharme, 1873).—Of the robust habit of growth, but the wood is unique, and something like that of the Victor Verdier race. Splendid foliage, most lovely when young in the spring, coming well up under the flower. Does not mind mildew much, and though not liking rain, can put up with it better than many of the light coloured Roses. The midsummer blooms are apt to come divided and badly shaped, particularly on strong shoots, but the good ones are fine in petal and fulness, fair in lasting qualities, and of the largest size. A fairly free bloomer, and as an autumnal simply the best H.P. we have, for flowers in September or even October are often better than those of the summer crop. A grand Rose if "well done by," grown on the Briar on rich strong soil, but rather dainty, and does not like the Manetti stock, or being starved.

Charles Lefebvre (Lacharme, 1861). synonyms, Marguerite Brassac and Paul Jamain.—Strong growth, with stiff smooth wood and fine foliage. The secondary shoots are much stronger than the early ones, and so with me on cut-backs the latest blooms of the first crop are generally the best. Rather liable to orange fungus and red rust, but not much to mildew, and can stand rain pretty well. Comes well as a rule, good in petal, centre, and size, lovely in colour, and beautifully smooth in general appearance. Open semi-imbricated shape, which is very effective, but not a good form to last. A free bloomer and good autumnal. This is the G. O. M. of crimson Roses. Longfellow's "Hiawatha" metre always seems to me to suggest

Charles Lefebvre, the
King of Roses.

Comtesse de Serenye (Lacharme, 1874).—Fair growth and foliage rather liable to mildew, and cannot stand rain at all. A free bloomer and good autumnal. A Rose that can be very fine when it chooses, but with awkward manners, for this is one of the coarse varieties, too full in petal, in regard to which the stronger you grow them the worse they are. On a maiden growth, especially if the buds be thinned, the survivor will often be a most unsightly object, and indeed it is very seldom that a large bloom will come without distorted shape; but on the side shoots of a cut-back in a dry autumn flowers of a beautiful "globular imbricated" shape may be got of good lasting qualities.

Countess of Oxford (Guillot, 1869).—One of a large family of smooth-wooded Roses, all, I believe, descended from Victor Verdier (1859). Some of them, such as the one under notice, *Pride of Waltham*, and *Marie Finger*, are quite first class. The different members of the family have the same or similar manners and customs. They have characteristic smooth wood and good foliage, which is most lovely in the early spring, not suffering much from mildew, but very liable to red rust, the early shoots being often quite bare of foliage by the end of August. They do not like light soil or the Manetti stock, but the flowers will stand rain fairly. *Countess of Oxford* is good in petal, fulness, and shape, and of the largest size, sometimes rather coarse. Fairly lasting in shape, but the colour soon gets dull, and is much

lighter on weak plants; a fairly free bloomer, but not so good an autumnal as some of the family. Decidedly liable to sport, *Pride of Reigate*, *Pride of Waltham*, and, I take it, *Monsieur Trieror*, a new Rose of 1888, having already appeared. A white sport of this variety, of which *Pride of Reigate* seems to give us hope, would be an acquisition.

Countess of Rosebery (Postans, 1879).—Of strong growth, with distinct smooth wood and good foliage. A little liable to mildew, but not much injured by rain. The blooms come pretty well, but the shape is not always very clearly defined. Fine smooth petals, full and of fair size. Only fair in freedom of bloom and as an autumnal.—W. R. RAILLEM.

(To be continued.)

EVENTS OF THE WEEK.—To-night (Thursday) the National Chrysanthemum Society's dinner takes place at Anderton's Hotel, Fleet Street, at 6 P.M. sharp, and a large attendance is expected. Many are now preparing for a holiday period, but a time of rest and enjoyment to some necessitates considerable activity and work on the part of many. A visit to the markets in London or in any large town gives a good idea of the business transacted at this time. Covent Garden Market in particular is crammed with all the good things of the vegetable world for consumption and ornament, and next Saturday will probably be a busy day. On Monday, Tuesday, and Boxing Day the market will be open, as the demand for cut flowers is great as this time of year.

— ROYAL BOTANIC SOCIETY.—The following are the arrangements for 1890:—Spring Exhibitions, Wednesdays, March 26th, April 23rd, gates open at 2 o'clock; Summer Exhibitions, Wednesdays, May 14th, June 11th, gates open at 2 o'clock; evening fête, probable date Wednesday, July 2nd, 8 to 12 P.M.; promenades, Wednesdays in May, June, July, commencing May 7th, exhibition and fête days excepted; lectures, Fridays at 4 P.M., May 9th, 16th, 23rd, 30th, June 6th, 13th; general meetings, for election of new Fellows, scientific discussions, &c., Saturdays, at 3.45 P.M., January 11th and 25th, February 8th and 22nd, March 8th and 22nd, April 12th and 26th, May 10th and 31st, June 14th and 28th, July 12th and 26th, November 8th and 22nd, December 13th; anniversary, Monday, August 11th, at 1 P.M.

— THE weather in the south of England has been variable during the past week, but generally dull, with occasional rain. The temperature is much higher, with S.W. winds.

— THE WEATHER IN THE NORTH.—For the past fortnight the weather in Perthshire has been very variable, showery evenings and frosty mornings repeatedly alternating. Frosts of from 2° to 8° have occurred, but generally mild, frequently drizzly, weather has prevailed.—B. D.

— A NEW NATIONAL CATALOGUE.—It is proposed that a new edition of the National Chrysanthemum Society's catalogue be issued as early as convenient in the coming year. This work will be aided materially if catalogues containing novelties for the select lists, with all corrections and additions, be forwarded at once to Mr. Lewis Castle, Hotham House, Merton, Surrey, and to Mr. George Gordon, 1, Stile Villas, Wellesley Road, Gunnersbury.

— WE are desired to state that the variety of *ONCIDIUM FORBESI* shown at the last meeting of the Royal Horticultural Society was from the collection of E. G. Wrigley, Esq., Victoria House, Dukinfield, Cheshire.

— A HORTICULTURAL Association entitled the CRIFFEL DISTRICT HORTICULTURAL ASSOCIATION has been formed for the parishes of Kirkbean, Newabbey and Southwick in Kirkcudbrightshire. The proprietors in this district have promised liberal support, and a large number of members have been enrolled, rules drawn up, and office-bearers appointed: these being President, Mr. J. Gibson, Sallowgairn; Kirkbean; Vice-Presidents, Rev. W. J. Rae Mainsiddle and Mr. J. Curr, Kindar Lodge, Newabbey; Secretary, Mr. S. M. Smith, Schoolhouse, Kirkbean; Treasurer, Mr. S. Arnett, Carsethorn, Kirkbean, and a representative Committee including the gardeners on the various

estates. The Association begins well and is a proof of the increasing interest in horticulture throughout the kingdom.—S. A.

— IRON EDGING FOR BEDS.—A correspondent, "T. F.," will be glad to be informed where the iron edging that is used in the Paris parks and gardens, instead of tiles, can be obtained in this country.

— WE are desired to state that MR. ROBERT SYDENHAM of Birmingham has added a seed department to the great business he has established in bulbs.

— GARDENING APPOINTMENT.—Mr. C. Roberts, for the past seventeen years head gardener and general manager at Highfield Hall, Leek, has been appointed head gardener to the Right Hon. Lord Hill Trevor, Brynkinalt, Chirk, Ruabon.

— THE SACRED LILY OF CHINA.—Just as we are preparing for press we receive from Messrs. Barr & Son bulbs of the floriferous Narcissus that is grown under the above and other fanciful names in China and Japan. Instructions for growing and flowering the plants in bowls accompany the bulbs distributed, which will probably be tried in many British homes.

— THE "WEEKS" POCKET BOOK.—Annually the great Chelsea firm of Messrs. J. Weeks & Co. distribute pocket books to gardeners and friends. We have been favoured with a sample of one of these handy pocket companions, and reciprocate the good wishes with which it is accompanied. Compact and substantial, these books will be found serviceable by the recipients of them throughout the coming year.

— OUTDOOR TOMATOES.—On page 436 "J. H. W." gives a very interesting article on the above, and I fully coincide with all he says especially in respect to restriction of roots. We had some plants placed in exactly the same position—namely, in front of a Melon house, the only difference being that ours were in 10-inch pots, nailed up to the wall in the second week of May. When the fruit was set we top-dressed with a mixture of loam and cow manure, and also gave plenty of liquid manure, and they finished a fine crop of fruit off.—R. KIRBY, *Oulton Hall*.

— POINSETTIAS FLAGGING.—As bearing on your reply to one of your correspondents in last week's Journal please permit me to say that searing the cut ends of the stems with a hot iron is an excellent preservative of the freshness of the bracts. This should be done as soon as they are cut. By inserting a poker in the bothy or other fire a man can do a lot in a short time. We have practised this method for some years with our large supplies, and have kept the bracts fresh for a fortnight sometimes. The freely exuded milky juice if not prevented exhausts the life out of them shortly. We used to dip the cut end in a small pot of dry silver sand. This will check it, but not so well as searing them.—H. J. C., *Grimston, Tadcaster*.

— POTATOES IN AMERICA.—It would appear from the following that the Potato supply of America is inadequate for consumptive demands, and that exports from Europe are considerable:—"According to the estimates of Mr. J. Dodge, statistician of the Department of Agriculture, the total area in Potatoes this year was 2,500,000 acres. The crop of 1888 was large, and prices ruled low. The average yield per acre for 1889 is only about 76 bushels. The imports of Potatoes for the year ending June 30th, 1888, were 8,260,000 bushels; 141,000 from Germany, 1,453,000 from England, 2,895,000 from Scotland, 617,000 from Ireland, 2,899,000 from British North America, 155,000 bushels from all other sources.—(*American Cultivator*.)

— TOMATOES IN AMERICA.—The Cornell University of New York, through its Agricultural Experiment Station, has recently issued a bulletin giving the results of many important experiments in Tomato culture. The following is a summary of points established:—The tests indicate that poor soil may tend to render fruits more angular. Varieties of Tomatoes run out, and ten years may perhaps be considered the average life of a variety. The particular points at present in demand in Tomatoes are these: Regularity in shape, solidity, large size, productiveness of the plant. The ideal Tomato would probably conform closely to the following scale of points: Vigour of plant, 5; earliness, 10; colour of fruit, 5; solidity of fruit, 20; shape of fruit, 20; size, 10; flavour, 5; cooking qualities, 5; productiveness, 20. The following recent introductions appear to possess merits for market: Bay State, Atlantic, Brandywine, Jubilee, Matchless, and perhaps Lorillard, Prelude, and Salzer. Particularly valuable for amateur cultivation: Dwarf Champion, Lorillard, Peach, Prelude.

— THE METEOROLOGICAL REPORT OF THE STRAITS SETTLEMENTS has been published for the year 1888, being the fifth year in which meteorological observations in the colony have been made the subject of a general systematic report. The temperature of the air ranged between 67.2° and 96°, and solar radiation varied from 81° to 179°; the lowest temperature on the grass was 61°. Rainfall observations were received from forty-one stations. The annual amount differs considerably in the various provinces, the mean of the stations ranging from 65.6 inches in Singapore.—(*Nature*.)

— EARLY ROMAN HYACINTHS.—The value of these charming flowers can scarcely be over-estimated at this season of the year. For wreaths, bouquets, buttonholes, and vase decoration they are simply invaluable, and for arranging with other plants in pots for house embellishment we find no other white flower to compare with them from the present time till Christmas. For the latter purpose we pot five bulbs into a 5-inch pot, keep them plunged in ashes in the open air till they have an inch of growth above the soil, when they are placed under the stage in an intermediate house, and covered with inverted pots for a few days; after the inverted pots are removed they are left in the same position for a couple of days longer, then removed to a shelf near the glass in a Cucumber house, where they remain, and receive plenty of water at the roots till the flowers are expanded.—H. D.

— EPIPHYLLUM TRUNCATUM.—This plant in recent years has been much neglected, as the majority have the idea that it is a greenhouse plant, and treat it accordingly with unsatisfactory results. It should be placed in the stove until it has made its growth, and when completed it can with advantage be removed to the greenhouse, or any other place of a similar kind, to ripen, and thence again transferred to the stove as occasion may require. It succeeds far better grafted upon *Pereskia aculeata* as a stock, and makes more rapid growth than on its own roots. If the stocks are about 8 or 10 inches high when grafted attractive plants are soon obtained. In one of the stoves here a *Pereskia* was planted a few years ago, which has entirely covered the back wall, and upon this has been grafted two varieties—viz., *coccineum* and *elegans*, which have grown with marked success. They have been flowering, and looked very beautiful. The best compost is a mixture of loam, leaf mould, and broken bricks.—R. KIRBY, *Oulton Hall Gardens*.

— AT The Brandries, Beddington, Surrey, the residence of W. Lindsay, Esq., there is a DISPLAY OF GLOXINIAS which at midsummer would be worth recording, but in the month of December appears to me unusual. The group consists of about three dozen plants, which measure rather over than under 2 feet through, with from three to five dozen expanded flowers, and numberless buds to take their place. Both blooms and foliage are remarkable for substance and size, while the former are varied in colour. The plants are mostly in 7-inch pots, the compost loam and peat half-and-half, with a fair quantity of coarse silver sand. The gardener, Mr. C. Ritchings, however, attributes the fine development of the specimens not so much to the soil as to a concentrated manure he has himself mixed, and which is used for the growth of most plants under his care. In the same stove house there are very large *Adiantums farleyense*, *gracillimum*, and *euneatum*, which are evidence of superior culture, and that there is a something which suits them admirably. Be this as it may, a market should be found for a plant stimulant alike beneficial to a hardy fruit tree or the most tender Fern.—H. SHOESMITH.

— VILMORIN, ANDRIEUX & Co.—To celebrate the great success obtained by the firm at the recent Paris Exhibition, where they were awarded three grand prizes, three gold, and one silver medal, Messrs. Vilmorin, Andrieux & Co. invited the whole of their employés to a banquet, which was held at the Salon des Familles, Avenue de St. Mandé, on the 15th inst., when 410 were present. Before the banquet a most interesting ceremony took place—viz., the presentation of a bronze statue, "David and Goliath," to M. Henry L. de Vilmorin (the head of the firm) on the occasion of his promotion to the grade of "Officier de la Legion d'Honneur." This *objet d'art* was accompanied by an address signed by 448 employés of the firm, congratulating him on the honour recently conferred upon him, also expressing the sincere respect and high esteem in which he was held by everyone. M. de Vilmorin, in a very graceful and eloquent speech, acknowledged the compliment paid him, and expressed the pleasure that his partners and he had in having around them such a vast assemblage of their people. The arrangements were admirably carried out by Messrs. Schneider & Michel, and the gathering proved a complete success in every way.

— **HORTICULTURAL CLUB.**—The usual monthly dinner and conversation was held at the rooms, Hotel Windsor, on Tuesday evening, the 10th inst., Mr. John Lee in the chair. There were present also Messrs. J. H. Veitch, Philip Crowley, H. J. Pearson, C. E. Pearson, A. J. Pearson, H. Veitch, W. Herbert Fowkes, James Walker, George Bunyard, J. H. Stott. The subject for discussion was insecticides and the best method of applying them. It was opened by Mr. C. E. Pearson, who gave a very interesting account of experiments tried with various insecticides, and afterwards Mr. J. H. Stott exhibited in operation his very ingenious invention for the distribution of insecticides, which was considered by those present as likely to be extremely useful. Mr. Bunyard stated that bitter aloes had been found much stronger and more efficacious for the destruction of aphides than quassia, and that the Cape aloes was much stronger than any other; the black fly on Cherries was considered the most difficult of all to deal with, and requires a stronger solution. It was stated by Mr. A. J. Pearson that great care must be exercised in the use of quassia and aloes in a vinery, as they once had a house of Grapes so tainted with the bitter flavour that they were useless. It was generally admitted that Stephanotis was also the worst plant for mealy bug, and that the best, if not the only way of getting rid of it was to wash the plant with methylated spirits used with a small camel's hair brush. A very interesting discussion took place, and Mr. Lee proposed a vote of thanks to Mr. C. Pearson for his valuable and interesting paper.

— **TUFTED PANSIES.**—This is a new name someone has given to our old friends the Violas, and I fail to see why. I have been a grower of the Viola for a number of years, certainly since Viola cornuta and Blue Bell were introduced, and I have been the raiser of True Blue, Mr. C. Turner, Queen of Lilacs, and other established varieties, and grow Violas by the thousand, and yet I fail to see why my old friends are called Tufted Pansies. Of Violas, as spring and summer decorative plants, it is impossible to write too favourably, and they are continuous bloomers from March until September and even October. The treatment is simple. Plant in favourable districts in October or November firmly and deeply. In less favoured districts plant in March or April, not later if it can be helped, in good soil, always firmly and rather deep. Such varieties as True Blue (Dean's), Countess of Hopetown, white; Bullion and Golden Prince Improved, both deep yellow; Ardwell Gem, pale yellow; Queen of Violets, purple; Countess of Kintore, The Mearns, a grand bedding blotched variety; Duchess of Albany, lilac and mauve; Elegans, lavender; Queen of Lilacs, blue and lilac, are only a few of very first-rate bedding varieties.—W. DEAN, *Florist, Sparkhill, Birmingham.*

— **RAILWAY RATES FOR POTATOES.**—An adjourned meeting of Scottish Potato merchants was recently held in St. John's Hotel, Perth, to consider as to further procedure in reference to the lowering of railway rates for Potatoes consigned to England. Bailie Whyte presided, and reported that the memorial agreed to at the last meeting had been sent to the goods managers of twenty-nine English and Scottish railway companies, but that very few of the latter had replied. The Midland Railway Company had answered that they would consider the matter favourably along with other companies. It was reported that the Secretary of the English and Scottish Traffic Rates Conference had announced that he could not arrange to receive a deputation, but that he would place the letter and memorial sent him before the meeting on 13th December. Mr. Thompson, general manager of the Caledonian Railway, stated that he had conferred with the general goods manager, and had asked him to assist the Potato merchants in the object in view. The goods manager of the Highland Company said the Scottish railways would be glad to have the assistance of the traders in seeking to get the rates reduced. Mr. A. Hutchison, farmer, said the carriage of Potatoes just now was equal to the value of the article itself, and that so long as that state of things existed very few could be sent by rail. Ultimately it was agreed that the railway companies should be further memorialised on the subject, and informed that the traders would be quite willing that the rates, if lowered, should be rearranged on prices rising to £3 per ton.

— **THE TREES OF CALIFORNIA.**—The coast range of mountains running through California, and fringing the western shore of the continent, is a great natural arboretum—a paradise of forest trees and flowering shrubs. North of Shasta the forests awe with their grandeur; south, the scenery is park-like and sylvan, and the shrubs are at home. Here can be found the extremes of tree growth. The hardy species of the north are not only neighbourly, but familiar, and even intimate, with the delicate representatives of the south. The resinous breath of

the Pine and Hemlock, Juniper and Fir, mingles on the same hillside with the spicy fragrance of the Bay tree and the perfume of the Balm. The evergreen Redwood rises, straight as an arrow, to a height of from 200 to 300 feet. There are whole tribes of the Coniferae, dozens of species of Cypress and Cedar, a variety and relationship of the Oaks that drives the botanist wild, ravines filled with the flowering Dogwood, sweeps of glistening Manzanita, spattered patches of the red-berried Buckthorn, rifts of the pink-petalled Rhododendron, sanguinary patches where stands the Judas Tree. In this favoured country also bloom and bear the Pomegranate, Fig, Olive, Almond, Apricot, Lemon, Orange, and the Nectarine. The Camellia is a tree, the Heliotrope a stout shrub; Geraniums are used for scarlet hedges; the Cala Lily is a weed. And to round out this riot of luxuriance—this saturnalia of foliage, fruit, and flower—Nature sows every spring, in and through it all, a crop of wild Oats such as was never even dreamed of by the original prodigal son.—(*Harper's Magazine*).

— **THE third annual dinner of the LIVERPOOL HORTICULTURAL ASSOCIATION** was held on the evening of the 14th inst. at the Bear's Paw Restaurant, Lord Street. There was an excellent attendance of members, upwards of 170 being present. The whole proceedings were marked with an enthusiasm and goodwill which speak well for the unity and welfare of the Association. The Chairman of the evening was Fletcher Rogers, Esq., the excellent and popular Hon. Treasurer. After the loyal toasts had been duly honoured, and the National Anthem sung with such vigour as gardeners only can sing it, the Chairman proposed the "Liverpool Horticultural Association," remarking that he claimed for the Society that it was a special benefit to the neighbourhood in which it existed. He at times viewed with regret the want of appreciation it met with, notably in the summer Show of the present year; but he rejoiced to know that the Society consisted of members who never knew defeat, and who, although there might be temporary discouragements, were determined to go on until success was achieved. Mr. White, Chairman of the Executive Committee, responded, and said the Committee had passed through a very depressing and anxious year. Although the summer Show was removed from Sefton Park to Fairfield, where it was thought it would be more accessible to the masses of the people, it had resulted in a considerable loss. He was happy, however, to be able to state that the public had recognised the excellence of the autumn Show, and had attended it in larger numbers than had been the case for several years. The subscribers still numbered about the same, and, encouraged by the success of the autumn Show, the Committee had arranged for a spring show for the ensuing year. He trusted there were brighter days in store for the Association, and that with the new year a more prosperous career would be entered upon. Other toasts followed, and a pleasant evening was spent.—A. R. C.

TRENTHAM.

OCCASIONALLY we read or hear something about Trentham, either in the way of a new variety of Orchid or of fruit; and this year Trentham is to the fore in the Chrysanthemum world. All branches of gardening have, for many years, been well represented there. Old gardeners remember Trentham in the time of Fleming; middle-aged gardeners have a recollection of it under the superintendence of Zadok Stevens; the rising generation will know it better under the management of Mr. Blair. Changes of various kinds have occurred, but gardening, it may be in different forms, is yet predominant. In spring, summer or autumn the gardens are always beautiful, interesting, and instructive, though some people will think they are more so in July than in November. "The old order giveth place to the new" at Trentham as elsewhere; old hothouses are rebuilt and modern improvements added where practicable; useless structures replaced by new ones on a better site, and "onward and upward" appears to be the watchword in more senses than one.

Improvements, in the strict sense of the word, are effected in the pleasure grounds and American garden as time permits and good taste and careful consideration suggest, not as some men do, by reversing and upsetting and altering everything done by their predecessors, but by thoroughly grasping the ideas and objects of the designing master mind and carrying them out now, years after, by reducing within proper limits the overgrowth permitted in previous years by uncontrollable circumstances; the lopping of a bough here and there, the removal of a tree grown too large and obstructing a desirable view, and by additional planting to complete, perfect, and, if required, to extend the original design; these are true improvements, and Mr. Blair exemplifies the correctness of his own artistic skill by recognising and conforming to the lines laid down by others.

The flower gardens are tastefully planted every summer, and the general keeping of the same is all that could be desired. Thousands of the Potteries people and from other towns avail themselves of the opportunity given by the annual flower show held in or near the

gardens to enjoy the gardens so generously thrown open by the Duke on that occasion; and that His Grace wishes them to enjoy the beautiful gardens is well proved by the interest and pleasure he exhibits as he mixes with the people. The magnificent house, the extensive lake, the covered walks, grand flower gardens, lawns, conservatories, &c., are so imposing that none but the most prejudiced can help admitting Trentham to be a beautiful and interesting, if low and damp, place, and to do justice to it would require a far abler pen than mine. I give a few notes of the gardens as I found them in the month of November, one of the most dreary months of the year, therefore they were seen in almost their duldest garb and not in their brightest.

THE GLASS STRUCTURES.

These if placed end to end would extend over a mile in length, consequently a detailed account of each house or its contents would take up too much of the valuable space of the Journal. The first entered is the early Peach house. The lights have been off all the autumn for the purpose of thoroughly maturing and resting the trees, or approaching rest as near as good culture will permit. The trees are clean, wood strong and bristling with buds nearly

by the way, having always been exceptionally well grown at Trentham. No. 7 is a vinery similar in size, &c., to the last, and is planted principally with Duke of Buccleuch, a noble Grape, unsurpassed in appearance, and scarcely in flavour, when well grown; but its unfortunate liability to "spot" in many places somewhat damages its reputation, and places it at a disadvantage with other Grapes of less sterling merit. No. 8 vinery is filled with late Hamburgs, which will carry the supply well into the new year, to be followed by the thicker skinned ones until the supply of new Grapes, from pot Vines, in May. This list does not exhaust the number of vineries at Trentham; but it gives a fair idea of the quantity, quality, and variety of Grapes grown there. It will be observed that, with all the space at command, the number of varieties is very small as compared with the number in general cultivation. Black Hamburg predominates, and is followed by Madresfield Court, Museat of Alexandria, Duke of Buccleuch, Lady Downe's, Gros Colman, Mrs. Pince, and Fosters' Seedling. There are several other varieties, but they are in a minority.

THE LARGE CONSERVATORY.

A rectangular structure with ridge and furrow roof and about 100 feet

FIG. 68.—THE GARDENER'S COTTAGE, TRENTHAM.

ready to burst, and they will be encouraged to do so on and from the 1st of December. The back wall of this house, as in many of the fruit houses at Trentham, is covered with Camellias, chiefly *alba plena*.

The next house is a vinery with a ridge and furrow roof, and called the Muscat house; it is 144 feet long and contains thirty-six Vines, the principal varieties being Museat of Alexandria (of excellent colour), Alicante, Gros Colman, and Mrs. Pince, good crops of each sort, and each sort a good example of its kind. Nos. 2, 3 and 4 vineries have had all the fruit cut and are resting. They are young Vines and have made wood of good quality, but fruit must be had, and they are taxed each year to the utmost. In No. 2 were thirty-three baskets of *Cœlogyne cristata*, most of them being 2 to 3 feet across, and all with fine pseudo-bulbs well set with flower spikes; these will be a splendid sight in the new year. No. 4 vinery contained some newly imported *Dendrobiums* having made extra strong growths during the past season at Trentham; these were *D. Wardianum*, *D. Freemani*, and *D. nobile nobilius*. No. 5 vinery is at rest and is filled exclusively with Black Hamburgs. No. 6 is a "glass ease" vinery 100 feet long, and is full of good useful bunches of Black Hamburg and Madresfield Court Museat, the latter,

square, more or less, I have not the exact dimensions. The objects that most attract the eye in November are the magnificent Camellias which form the chief occupants of the house. It has been my privilege to visit Trentham Gardens at intervals during the past twenty years, but I never saw the fine collection of Camellias in such splendid condition as they are this year. Perfect pyramids from 8 to 14 feet high are planted all over the house; all are in perfect health, and every one studded with flowers or flower buds. Where all are so good it is almost impossible to particularise; but there is one plant that commands special admiration; it is a gigantic specimen of *Camellia alba plena* 14 feet high and 30 feet in circumference, and covered from summit to base with flowers or buds and luxuriant foliage. The varieties comprise *alba plena* in quantity, *candidissima*, *Lady Hume's Blush*, *Bealei*, *Chandleri*, *Chandleri elegans*, *Donckelaari*, *Jubilee* and others. There is a good specimen of *Luculia gratissima* in this house, and during the winter months its large trusses of rosy pink and fragrant flowers are very showy and useful. Those people who know this plant will understand its value; others who do not, but who have plenty of head room for large Camellias, should obtain several plants of it from their nurseryman.

THE PEACH CASE.

A lofty but narrow, though roomy enough, structure devised for protecting Peach trees, &c., on walls at a minimum cost of money and of ground space, but at the same time giving the same command and the same facilities as the ordinary Peach house. This glass case is 600 feet long, in two divisions; the back wall is planted with all the approved varieties of Peaches and Nectarines and bearing good crops in their season. At the time of my visit the fruit and foliage was nearly all off, and tall grown Chrysanthemums were standing before them. The front of the case is well trellised, and on the trellis are grown young Peach trees that are annually dispersed throughout the length and breadth of the kingdom, Trentham having been noted for years for its well grown fruiting Peach trees. In the second division are eighty trees of Calville Blanche Apples in pots, each tree bearing a few very finely grown and coloured fruits. Apparently, and after careful examination, these trees (so juvenile do they look) are about fifteen years old; inquiry proves them to be between forty-five and fifty years old! The uninitiated must not suppose them to be gnarled and large trees in correspondingly large pots, far from it. They are trees that the inexperienced might, without appearing foolish, take to be five or six years old, and are in pots about 12 inches in diameter. In fact, the trees, with their fruit on, are frequently used for decorating the dinner table.

THE PLUM HOUSE.

At a right angle to the Peach case, and bounding the top of the enclosed kitchen garden is another range of glass, the first division being devoted to the Plum. It is 80 feet long, and is planted front and back with Plum trees. Mr. Blair is noted for his Plums, and takes first honours easily wherever he exhibits them. The varieties grown in the house are Ickworth Imperatrice, Dennison's Superb, Coe's Golden Drop, Reinette Claude de Bavay, Golden Emperor, Jefferson, Transparent Gage, and McLaughlin's Gage. Passing through one of the vineries we enter the Cherry house (which is a division of one of the long glass cases near the gardener's residence, and used for Vines, Peaches, &c.), trees are planted back and front, and the wood is strong and clean, and covered with large flower buds which, in due season, will produce very fine fruit in great abundance. It is to be noticed that Mr. Blair does not overcrowd his fruit trees with young wood during summer and autumn, only to be cut out in winter; but he thins the young shoots freely during the growing season, and leaves little more than will be required for bearing fruit the following year. That is a practice followed by all the best gardeners. If the most regular crops and the finest fruit be desired from any tree, the shoots must be so distributed that each leaf may receive unobstructed solar light upon the whole of its upper surface; all foliage in excess of that, or which smothers other foliage, indicates so much comparative waste and surplus wood, the smothered portion being weak in vitality, immature, and worthless. Therefore the golden rule is:—Allow just as much foliage, and no more, as will fill the allotted space without crowding, and allow the sun to shine upon and between all the leaves; this applies as much to Vines as to Peach trees, Plum trees or Cherry trees. The varieties cultivated in the Cherry house at Trentham are Bigarreau Napoleon, Black Tartarian, May Duke, Rivers' Early, Governor Wood, and Black Circassian.

At the top end of the kitchen garden is a block of span-roofed houses built after modern ideas, several by the late Mr. Stevens, and several recently by Mr. Blair. All are substantial and roomy structures of equal length, and each house in two divisions, but vary in width and in height. The first division we entered is used as a Palm house, the central portion being occupied chiefly with Kentias and *Cocos plumosa*, fine useful specimens 8 to 12 feet high. The side shelves are occupied principally by smaller Palms and a large quantity of *Anthurium Schertzerianum*. On the roof are fine specimens of Pitcher Plants (*Nepenthes*). In this house and a corresponding house Mr. Blair has adopted a somewhat unique method of keeping a moist atmosphere. The usual practice is for the man in charge to damp the pathways of such houses so many times a day by means of a watering pot. This has been dispensed with, and a small water pipe is carried along the front of the stages next the path, and this pipe is perforated at intervals with pin holes. By turning a tap the water is discharged through the pipe at any desired pressure, and may either be arranged to run slowly all day and night, or may be turned on with greater force for a few minutes. By these means the alternate damping and drying of the usual system is avoided, and an equable atmospheric moisture sustained. That the plants like the treatment is amply demonstrated by their luxuriance and cleanliness.

The next division is the *Cattleya* house, and consists of a large central stage with a water tank underneath and side shelves. The chief occupants of the centre stage are a grand lot of *Lælia purpurata* showing ninety flower spikes. Considering the short time since these were imported, it is probable these plants could not be surpassed for size and health by any in the country, and the same may be said of the scores of *Cattleya Mendeli* accompanying them. On the side shelves were fine examples of *Cymbidium eburneum*, *C. Lowianum*, *Zygopetalum Mackayi*, *Vanda cœrulea*, a handsome variety; *Barkeria melanocaulon*, and a grand lot of *Lælia anceps* and *L. anceps Dawsoni*, all showing 112 flower spikes, which will probably be a grand sight by the time these notes appear. The next house is occupied with winter Cucumbers, amongst which is a very nice seedling raised by Mr. Blair, and more will probably be heard of it. In some small frames in the interior of this house the earliest Lily of the Valley and Hyacinths, &c., are forced. Mr. Blair makes a

point of having his first Lily of the Valley by 17th November. The next division is filled with hundreds of beautiful plants of *Poinsettia pulcherrima*; these will be a sight worth a long journey to see. I am told these occasionally receive a sprinkling of nitrate of soda.

The second Palm house is a counterpart of the first, the contents being somewhat varied, amongst which are splendid plants of *Areca lutescens*. In the third Palm house are quantities of *Eucharis grandiflora* and *Pancratium fragrans* growing luxuriantly as an undergrowth to the Palms above them. The best specimens of *Eucharis* I have ever seen have always been grown under constant partial shade and in warm quarters; it is impatient of prolonged low temperature and strong sunlight. Hanging next the glass in this house was a very fine lot of *Dendrobium Jamesianum* ripening off their new growths, which were very strong for newly imported pieces, but all the Orchids at Trentham are in the best of health.

The next house and parallel to the others is a span-roofed Peach house, filled underneath the trees with a very fine lot of trained Chrysanthemums, and the adjoining division is planted with Roses and Tomatoes alternately, and the borders are filled with scores of strong useful plants of Arums. The favourite Tomato here is Hackwood Park, a variety difficult to surpass, all points considered. The last house of this block we enter is the Fig house, and the trees are planted on each side, the favourites being Brown Turkey and Negro Largo. The next division is used as a greenhouse, and is at present filled with dwarf-grown Chrysanthemums, 2 to 4 feet high, and carrying three to six good flowers.

FLOWERING ODONTOGLOSSUM HOUSE.

Those who have seen this at its best will not require convincing of its loveliness or of the health and vigour of the plants. It is a lean-to house with a north aspect, and about 90 feet long, and for quality of flower, general size, and healthiness of plants probably cannot be surpassed in the country. November is not the time to see an *Odontoglossum* house in full flower, but having seen this at other times I venture to say it is not possible by any word-painting to adequately describe its beauty. Hundreds of spikes of *O. Alexandra*, *O. Pescatorei*, *O. Rossi majus*, *O. Insleayi*, *O. triumphans*, *O. Halli*, *Oncidium macranthum*, *O. Forbesi*, *Epidendrum vitellinum*. These and others greet the eye at different periods, and the year round this house is well worth seeing. There is a mirror on the door at either end of the house, and the walls about these are coloured blue, which gives a very pleasing effect, more so than will be credited without being seen. The mirrors reflect the house and contents, and looked at one or both ways is apparently doubled or trebled in length.

Leaving this interesting house, we enter some of the pits devoted to growing small plants in thousands. In the first pit are healthy lots of *Dracena rubra* (true), *Kentias*, *Aspidistras*, *Asparagus plumosus nanus*, a grand batch of *Adiantum fragrantissimum*, *Anthurium Andreanum*, *Phalenopsis violacea*, *P. amabilis*, and *Dendrobium Brymerianum*; the latter there is a great quantity of first-class plants. In pit 2 we saw some *Dendrobium Ainsworthii* and *D. Ainsworthii roseum*. Mr. Blair knows when he has a good thing, and he loses no time in increasing it, and growing it in the best possible manner. Scores of pots of *Pleione lagenaria* (Indian Crocus) are on the shelf next the glass, and are pushing up their flowers from beside their flask-shaped pseudo-bulbs. In an adjoining pit are dozens of *Bouvardias* covered with flowers and flower-buds, and for general health cannot be excelled.

Other houses and pits are devoted to the establishment and culture of newly imported *Odontoglossums*, which are grown in tens of thousands. That the houses and treatment they receive is amply demonstrated by the stiff deep green and clean appearance of the plants collectively and individually, large and small. In the *Odontoglossum* and *Masdevallia* house at the back of the old Melon ground are several unusually strong plants of *Oncidium macranthum*, and fine lots of *Odontoglossum cirrhosum* and *Masdevallias*, the chief species of the latter being *M. Veitchii*, *M. ignea violacea*, *M. Davisii*, *M. Shuttleworthii*, *M. Harryana*, *M. regalis*, *M. rotundifolia*, *M. Chelsoni*, *Thompson's Scarlet*, and *Bull's Blood*. These are only a portion, and for size and healthiness they must be seen to be appreciated. The original *Odontoglossum* house, and which yet contains the original *Lapageria alba* on the back wall, is being furnished with a new roof and front, and will probably be used as such for very many years to come.

THE LAPAGERIA HOUSE

Had thousands of flowers hanging from the roof during September and October, and it must have been a very unusual sight. Every square foot of the large roof is covered with luxuriant growth. The aquatic house does not look as it used to when aquatic and semi-aquatic plants were grown in and over the bank; but the back part of the house is as pleasing as ever, if not more so. Bananas (*Musa Cavendishiana*) occupy their old home, and keep up an almost endless supply of their rich fruit. They are as strong, and possibly stronger, than usual.

Several other ranges of houses have been raised higher by Mr. Blair, and are filled principally with miscellaneous stove plants for decorative purposes, and with a large quantity of *Cypripediums* (Lady's Slipper) of all the best species and varieties.

THE CHRYSANTHEMUMS.

These have been a great feature at Trentham this autumn, and specimens of the general quality have been seen at most of the principal shows in England, where they have occupied very honourable positions.

The most notable is Mr. Blair's success at Hull, when he won the coveted challenge vase and also a silver cup in another important class, which is a stroke of business seldom equalled at a similarly important exhibition. About 3000 plants have been grown at Trentham this season. Of that number 700 were grown for producing large blooms; the remainder consisted chiefly of dwarf plants 2 to 4 feet high, but the bulk of them 3 feet, with three to six good flowers, and suitable for general decorative purposes; and a large number of specimen plants fit for any exhibition, the remainder, comparatively few in number, roughly grown for cut flowers. Such a large quantity of plants occupy a considerable amount of space, and numerous houses were filled with them. Collectively they have made such a show that probably could not be seen in any other private garden in the kingdom, and possibly in very few trade establishments where the plant is a specialty, if quality as well as quantity is taken into consideration. Many of the newest have had a good trial, and most of them have turned out all that could be desired. Among the incurved may be mentioned Violet Tomlin, Miss Haggas, Mr. Shoesmith, W. K. Woodcock, and Lord Eversley as new and of good quality; whilst older varieties were represented by hundreds of first-class blooms of Empress of India, Golden Empress, Queen of England, Alfred Salter, Emily Dale, Lord Alcester, Bronze Queen, Lord Wolseley, Prince Alfred, Mr. Bunn, White Beverley, and John Salter. Amongst the Japanese, the new varieties were well represented by Stanstead White, Buttercup, Condor, Etoile de Lyon, Mrs. J. Wright, and C. Cannell; and quantities of first-class blooms of Belle Paule, Mad. C. Audignier, Meg Merrilies, Ralph Brocklebank, Mdle. Lacroix, Avalanche, Fair Maid of Guernsey, Balmoreau, E. Molyneux, Criterion, J. Délaux, Golden Dragon, Lady Selborne, Mad. J. Laing, Val d'Andorre, and Thunberg. Much credit is due to Mr. Murk, who has attended to the requirements of the Chrysanthemums from first to last.

In the walled-in kitchen garden all the quarters are occupied with vegetables and salads for winter consumption; not a square foot of ground is allowed to be unoccupied. Thousands of Celery are grown, and Major Clarke's Red is the favourite. Three or four thousand plants are grown in pots for forcing, and a fine batch they are, with fat plump crowns. The kitchen garden near the American garden is a novelty in design. There is nothing elaborate about it, but is simply a circular piece of ground which, until recently, had a tank in the centre; but this is now filled up, and forms a central turning point for the small waggons used in these extensive gardens; the paths radiate from the centre, and the ground is thus divided into segments of a circle. This ground is also occupied with winter vegetables, chiefly Brussels Sprouts and Broccoli. Potatoes are grown in a field, and the staple supply of Apples comes from an orchard at a distance from the gardens. The total area of gardens, including orchard, under the charge of Mr. Blair is nearly 100 acres, and all departments prove that he is master of his work. The pretty house in which he dwells is shown in the engraving on page 533.—VISITOR.

POINCIANA REGIA.

THERE are two well-marked varieties of this magnificent flowering tree in the East Indies, though I cannot say whether they are permanent or not. One has scarlet and yellow blossoms, and the other crimson and white. The former seems to be the most common, and is abundant at Madras, Secunderabad, Rangoon, and other places, while the other prevails chiefly at Bangalore. Whether due to the climate or not I am unable to state, but it appeared to me that the foliage of the Bangalore plants was richer and more profuse, and consequently much more beautiful, than any that I saw elsewhere. Indeed, the luxuriance of the trees generally on the Mysore plateau seemed to indicate that there they had found conditions of soil and climate eminently favourable to their most perfect development. There are, however, many large and noble specimens at Coimbatore, near the foot of the Nilgherries, and in May the road close to the town was all aflame with their gorgeous flowers. No object in the whole vegetable kingdom can, in my opinion, vie with this splendid Poinciana in the radiant wealth of its peerless bloom—not even the far-famed and glorious *Amherstia nobilis*, which I have seen in great perfection at Rangoon and Moulemein, in Burmah.

I have now and then heard the Poinciana regia called the Ostrich-feather Tree, without doubt on account of its beautiful foliage, which has much the appearance of broad spreading plumes; and at Bangalore it is occasionally known as the Flame of the Forest; but this name, though by no means inappropriate, is the prior property of another brilliant plant, the *Ixora coccinea*, to which it is also very applicable. Sometimes in India the term Gold-Mohur Tree is used to specify the Poinciana under notice, though it seems to be really owned by the yellow species *Poinciana elata*; and the name of Flamboyant is familiar to those who have seen the tree at the Mauritius.

Poinciana regia has apparently only been found in a wild state in Madagascar, whence it made its way many years ago to the Mauritius, and subsequently further east. It belongs to the Natural Order Leguminosae, and the genus was named by De Candolle in honour of M. de Poinci, once governor of the Antilles.—G.

CIVILISATION AND PLANT LIFE.

At a recent weekly meeting of the Richmond Athenæum, Mr. R. A. Rolfe, A.L.S., read the following paper on "Civilisation Viewed in its Influence on Plant Life." Mr. E. King presided.

If we reflect for a moment on the number and variety of the products derived from plants which minister to man's daily needs, as food

clothing, and medicine, we can form some little idea of our indebtedness to the vegetable kingdom for the very means of subsistence. Our own supplies are brought from almost every clime under the sun, and we have become so accustomed to existing conditions, and regard them so much as a matter of course, that I question whether any of us can realise what the effect would be if England were isolated from the rest of the world for a few short weeks. The production of these vast supplies of food, and other necessities and comforts of life, entails the laying under cultivation of large areas of the earth's surface, and a corresponding displacement of the plants which would otherwise occupy the ground. How great this displacement really is would be difficult to estimate, and perhaps it can best be expressed in few words by saying that agriculture is the greatest and most important of all industries. There is no tradition, no written history, to tell us at what time man began to till the land, but fortunately there are other data from which pretty satisfactory evidence can be obtained. In order to discover the first distinct traces of the culture of the fields we must go back to the time of the builders of the Swiss lake-dwellings of the neolithic age. At this epoch we have evidence of the cultivation of five distinct kinds of Wheat and three kinds of Barley, also two other cereals. Apples—wild and cultivated—have also been found, together with remains of the Pear, Cherry, Plum, the wild Sloe, Peas and Beans, Hazel and Beech nuts, Acorns and Chestnuts, the Blackberry, Raspberry, and Strawberry, the Poppy, Flax, and possibly of two or three other plants of economic use. Even remains of bread and carbonised cakes of Poppy seed have been found, and in one locality several bushels of Wheat were discovered heaped up in one place, evidently the provision of some family or tribe. Flax was extensively cultivated, for pieces of rudely woven cloth and balls of flax thread, string, and cord, have been found, also the rude looms in which the cloth was woven. Numerous hand mills for pounding and grinding the various cereals are among the relics of these ancient cities. The bread had evidently been baked between hot stones, and was found in the form of little circular cakes, 4 to 5 inches in diameter by 1 to 1½ inch thick. It was unleavened, and I need scarcely add that wholemeal bread was then the order of the day. A cake made from the seed of the garden Poppy has also been found, reduced to a cinder. By whatever means agriculture was first instituted, it has certainly progressed and multiplied enormously, and even before the historic period several plants were very widely cultivated, of which may be noted especially Wheat, Maize, the Sweet Potato, several Millets, and Tobacco.

Having spoken of the three great centres in which agriculture apparently originated—namely, the East, China, and Tropical America, the lecturer said the indirect effects of the extension of agriculture are of two kinds—first, the diffusion of a host of weeds, which in various ways are introduced with the plants cultivated by man, though much against his will; and second, the spread of certain economic plants beyond the area in which they have been planted, owing to the climate and situation being especially suited to their requirements. Perhaps the two classes are not strictly separable; at all events, our European Watercress is an example of a useful plant introduced into New Zealand with the best intentions, but which, like the rabbit in Australia, has increased to so prodigious an extent as to choke up the streams, and altogether has developed into an unmitigated pest. It is clear that if any given plant is found to be useful to man, and to become the subject of extensive demand, then the natural supply at once tends to diminish, and the only way to keep up the supply is to bring the plant under cultivation. In the second place we see that man's requirements are so extensive, and have such a tendency to increase, that more and more land is continually being brought under cultivation, with the inevitable result—however much we may regret it—that many of the most charming spots on the face of the earth are being destroyed by the axe and plough, many of Nature's wildlings are gradually becoming more restricted in area, and some of them must eventually become as extinct as the dodo; indeed, there are grounds for believing a few are already extinct. In the third place we see that others of their fellows benefit by the operations of the agriculturist, filling up the ground prepared by him for more useful crops, and generally defying him to do his worst—hence the unrelenting war waged against them. And lastly, we see how the great law of evolution comes into play, and in the hands of the cultivator becomes one of the most useful servants of mankind by increasing his food supplies or adding new beauty to the plants he cultivates for ornament.

In conclusion, a few thoughts as to the needs and possibilities of the future. The world's timber supply is rapidly becoming one of the burning questions of the day. The utter recklessness with which whole districts have been denuded of their splendid forests has been universally regretted, and especially when this destruction has been followed by a distinct deterioration of climate—a fact which has been recognised over and over again, both in America and elsewhere. Perhaps much of this destruction was inevitable, though none the less to be regretted on that account, especially when one remembers the vast quantity of valuable timber which has been committed to the flames simply to get rid of it, and thus practically wasted. The question of reforesting certain districts is now one of the questions of the day, and one which must be solved in the near future. Indeed, much good work has already been done, and one cannot help viewing with admiration the practical recognition of this need of the future by the Indian Government, the success with which the Indian Forest Department has been organised, and the good work it has already effected. It is perhaps not too much to say that in the near future arboriculture will take its place beside its sister industries, agriculture and horticulture, in a way that has never been

seen before. The influence which civilisation has exerted on the vegetable kingdom has not always been a beneficent one, yet by working in harmony with the great law of evolution it has showered untold blessings on the whole human race.

The Chairman said that the destruction of timber in various ways in Switzerland was having an effect on the climate, and in time some steps might have to be taken to counteract the effect. Mr. Baker, of Kew, deplored the great harm that had been done by man to the most beautiful parts of the earth. The results of man's care and attention to certain kinds of plants was illustrated in the numerous varieties of the Chrysanthemum, and also in the many kinds of Apples which were widely different from the wild species. Mr. Miller spoke of the influence which animals exerted on plant life, and amusingly traced the effect of the existence of old maids on the supply of Clover. Clover, he said, was fertilised to a great extent by humble bees; the number of humble bees was affected by the number of field mice, the number of field mice by the number of cats, and the number of cats by the number of old maids. (Great laughter.) Mr. Morris, of Kew, said that much harm was done to the productiveness of soil by the destruction of forests in tropical countries. The ground was exposed to the heat of the sun, and this led to great evaporation and aridness. In this country many more trees were cut down than were planted, and in time, if this went on, it might produce a change of climate. Not only might the growth of necessary products be affected, but the beauty of the scenery and the health of the climate, for both of which it was necessary that there should be trees growing wherever possible. Mr. Wakefield thought that in the Thames Valley a few trees could be spared, as it might have the effect of making the atmosphere less humid and relaxing. Mr. Jackson pointed out that besides the large amount of timber that was cut down in order to clear the ground for cultivation, much was also used up in the making of india-rubber and turpentine. Dr. Wilson said that in New Zealand he found that the European grasses were driving out the native grasses, to as great an extent as the Europeans were shouldering out the Maories. A hearty vote of thanks having been accorded to Mr. Rolfe for his paper, he briefly replied.

THE NATIONAL CHRYSANTHEMUM SOCIETY.

THE last Floral Committee meeting of the year was held at the Royal Aquarium, Westminster, on Wednesday, December 11th, at 2 P.M., when Mr. R. Ballantine took the chair, and the following members were present:—Messrs. E. Sanderson, G. Gordon, L. Castle, R. Dean, H. Cannell, F. P. Kendell, J. Wright, C. Gibson, R. Owen, G. S. Addison, J. Mardlin, C. Swift, T. W. Boyce, and T. Bevan.

For so late a date there was a good number of exhibits, Mr. R. Owen contributing a number of new varieties, amongst which were the following:—White Elephant, a Japanese, somewhat like James Salter, of a purplish tint, but whether this was due to the age of the blooms or the late period could not be determined. The Japanese W. W. Cowles was again shown, but though the colour is good the blooms were not sufficiently developed in the centre to merit an award; the Committee, however, desired to see it again. The variety is evidently a promising one, for we have seen fine examples in the north of England this season, but a committee can only judge of a variety by the specimens submitted, not by its reputation. This point has been frequently discussed, and exhibitors should bear in mind that the condition of the flowers shown is all there is to guide the members to a decision. Mr. Owen also had a Japanese named Mrs. J. Wannamaker, to be seen again, and Mrs. J. Clarke, regarded by some as much like Volunteer. A vote of thanks was accorded for the collection. Mr. Taylor, gardener to Sir J. Lubbock, High Elms, Down, Kent, also had a collection of fresh Japanese and incurred flowers (vote of thanks).

At the conclusion of the ordinary business, the Committees had some other duties to perform, upon which they entered with considerable zest. It was decided at a general meeting earlier in the season that it would be more convenient if the Floral Committee were entertained at a luncheon on the conclusion of the year's work than at the Judges' luncheon on the day of the November Show, when the bustle and confusion render attention to such matters a rather painful duty. Accordingly the full force of fifteen elected members assembled to prove the wisdom of the decision, and they evidently accomplished the very easy task entirely to their own satisfaction and that of the projector. Several eloquent speeches were delivered by horticultural orators of repute, graceful compliments were showered down upon the officials, and Mr. Cannell discoursed fluently and instructively upon the present high position of the Chrysanthemum, the work of the National, the wide extension of interest in the plant, and cognate matters, treated, of course, in his usual trenchant manner. The Hon. Secretary was "toasted," the Chairman was similarly treated, both responding in touching terms. The venerable and venerated past President expressed a wish that the Committee would continue its useful work, and a neat piece of Gordonian oratory in reply, admirably rendered the best intentions of the members

to justify all the good things said of them. Then, as they say in the daily papers, "the proceedings terminated," for the Chairman and Secretary are busy men, and it was not until a late hour that they were enabled to cast aside the cares of office.—M. N. C. S.

PROBLEMS IN CHRYSANTHEMUM CULTURE.

[A Paper read by Mr. J. Wright at Hull, Nov. 21st, 1889.]

(Continued from page 513.)

POTTING, WATERING, AND FEEDING.

THESE are factors of the highest importance in contributing to success in the cultivation of Chrysanthemums. The triune subject can only be treated in general terms, and concisely, as to go fully into the matter would absorb time that can be better occupied by others in discussion. Briefly, then, I think the tendency amongst persons who have not been trained by masters in the art of plant culture is to err in overwatering in the early stages of growth, and again when the blooms are opening and during their period of beauty; and to err in the under-watering during the bright, dry, sultry days of summer, when the pots are crowded with roots and the sun extracting moisture from the foliage faster than it is supplied from the soil. I do not suggest that all amateurs make these mistakes, but I know they are common; and I am not able to say that all gardeners avoid them, but I know that some do, and these are they who score the greatest triumphs in public competition. A valuable prize was never yet won in keen competition that was not the result of close attention to small details in routine rather than by the adoption of some new method, or the use of some fertilizer unknown to the rest of the world. Many a mistake has been made in repotting: when the ball of soil containing the roots was either too dry or too wet. If too dry no amount of after watering can make amends for the error; and it is impossible to give enough for moistening the central lump of old soil without spoiling the new; while if the old is too wet, a stagnant mass, the new soil will in all probability become stagnant too. At any rate, the sluggish roots cannot take free possession of the new compost and imbibe what it may contain for the support of the plants. I desire to impress on all who are inexperienced, be they amateurs or gardeners who are employed in shifting the plants, the absolute necessity of avoiding the serious mistakes alluded to.

The ball of soil when turned out of a pot for placing in a larger should be decidedly moist, yet not distinctly wet, and the soil to be used must be damp enough for compression, while it does not adhere unpleasantly to the hands. When in the right condition it can and should be pressed down as firmly as the old, for two reasons. First, because firmness causes, by the force of resistance, a multiplication of roots; and, secondly, because the greater the bulk of soil in a pot the greater the quantity of food it contains. The character of the growth resulting from those provisions of great root subdivision and adequate nutriment in the soil directly promotes firm short-jointed growth under favourable conditions of watering and position, in contradistinction to the frothy growth that follows when a few strong roots strike through a comparatively loose bulk of soil. These remarks have a direct bearing on watering and feeding, as I will show in a moment. By firm potting the soil does not become dry nearly so soon as when the soil is loose, and consequently water in the former case is not needed nearly so often. Therefore, and this is a point worth remembering, much food is retained under the first practice, and appropriated by the plants, that is washed out by the second with the oft recurring drenchings.

"But surely," some may be mentally remarking, "the soil can be made too firm, especially for young plants." It can, and for large plants too, but not if it is in the right mechanical condition. Nothing incites the multiplication of roots in young plants more than sweet leaf soil, not made from fermented but unfermented leaves, and nothing better retains moisture for those roots. Add to it an equal bulk of loam with a suitable admixture of sand and crushed charcoal, also a slight dredging of powdered superphosphate or steamed bone flour, and it will not be easy to pot too firmly, while the food will be suitable for the infantile plants. Phosphatic, or bone manures, are good all through the season, and their quickness of action depends on their fineness; for wearing well in larger pots they should be coarser, and they thus exercise a good mechanical as well as chemical effect. In all cases it is desirable to incorporate the manure in the soil, which should be damp, at least a month before using. Potash is essential, but if Clover abounds in the turf that is cut for storing, the soil will contain sufficient of that material. If there is no Clover, give an occasional light dredging of crushed saltpetre, or mix a 5-inch potful in a bushel of the compost with the same quantity of bone meal. Some special manures contain those important ingredients in due proportion, with the addition of a more active stimulant, and those who have found the preparations satisfactory cannot do better than adhere to them. Lime is a necessity, as is sulphur, and both are combined in sulphate of lime or gypsum, and this may be used similarly to the other ingredients. Observe all those mentioned are foods, not merely stimulants. They are the bread and beef, so to say, of plants, while the nitrogenous manures, such as nitrate of soda and sulphate of ammonia, are more analogous to wine and whisky. I think some doctors recommend these to Chrysanthemum growers that are low, while they are sometimes believed to do good if not ordered, and are taken accordingly, but moderation is a golden rule to remember, and so it is in giving active stimulants to Chrysanthemums.

Reverting to watering. It is too much the custom to drench the soil as soon as plants have been shifted. Much better is it to syringe

the foliage for a day or two to prevent evaporation than to saturate the soil before root movement commences; but flagging must not be permitted through lack of moisture at the roots. When the soil is too dry the roots shrivel, when too wet they decay, the result in both cases being the same—plant enfeeblement. Avoid the two extremes, and healthy growth follows. Injury is often done to Chrysanthemums by heavy and continuous rains occurring just as the final potting is completed in June. Ample drainage and raising the pots from a close wet surface minimises the evil.

Fresh surface roots induced by a generous top-dressing when the petals are forming are of service, with judicious feeding, superphosphate of lime dissolved in soot water being good at this stage. I must leave practical cultivators to say what else is needed on this subject. I am going on too long. When plants are housed the syringe is often of more use than the water pot for a few days, and root stagnation must be particularly guarded against; but so must drought, though I have seen many plants kept too wet at the roots in October and November. Attending to Chrysanthemums well is intellectual work, and reminds of the famous agriculturist who, when asked what he manured his crops with replied, "Brains, sir, brains;" and you may depend upon it there is nothing like brains for Chrysanthemums.

THE DAMPING OF BLOOMS.

Nothing is more disappointing than to grow Chrysanthemums for a year, produce handsome blooms not long before an exhibition, for which they may be reasonably expected to "keep," then in a night to find them suddenly and unexpectedly collapse, blackness and decay following freshness and beauty as if at a bound. The great scourge known as damping has ruined the blooms of the best of Chrysanthemum growers—men who have adopted the best means known to them for their preservation. That being so renders it obviously the more difficult to assign a cause for the misfortune that can be expected to meet with anything like general acceptance. It were useless discussing remedies, for there are none. It is not in the power of man to restore freshness to a decaying flower, and therefore our whole resources should be directed towards ascertaining the origin of premature decay in the hope that counteracting influences may be provided for its prevention.

In endeavouring to do this difficulties present themselves at every step, and as soon as one person sets up a theory another knocks it down. Some varieties are more prone to the affection than others is an opinion widely entertained, and often, and probably with truth, expressed. At the luncheon after the Kingston Show Mr. Furze, who won the twenty-five-guinea cup there, recounted his experience. The blooms were examined on a Saturday night, fresh, bright, and beautiful, and hopes were bright and hearts gay; but during the night the damp fiend took possession, and on the Sunday morning nearly all the best blooms—it is always the "best" in these calamities—were ruined. The days had been dry and cool previously; the fatal night was damp and murky. We may, therefore, wonder the less at the great misfortune, but what puzzled the owner of the plants was this—those varieties that had been the first to "go" in previous years were the least affected, while those which usually escaped were the most seriously injured. He regarded the whole question as mysterious, and almost seemed as if he would be glad to give a medal to anyone who could solve the great problem of damping.

It was not the varieties as such that escaped on the one hand, and were overtaken on the other, but the condition—the differing condition—of the florets that caused one bloom to withstand what another could not endure: age, substance, and possibly colour having some influence in the case. The hard florets of Avalanche, for instance, would stand firm against the enemy, whilst the comparatively flimsy petals of Edouard Audiguier would succumb; and the colour of the latter would weaken rather than strengthen it in its contest with damp. Have you not observed that when the first brisk frost sweeps over gardens in autumn, killing not all, but most tender flowers, that the darker coloured are the first and most affected, the whites the last and the least? Call to mind any kinds you like—Dahlias, Verbenas, Asters, Zonal Pelargoniums, no matter what—the whites remain fresh when many of the darks are decaying. Why is this? Is it not because the radiation of heat from dark surfaces is greater than from light, the former thus remaining the colder? The darks both absorb heat and lose it quicker than the lights do, and as it is the last feather that breaks the camel's back, the featherweight by which dark flowers are handicapped when the strain comes breaks them down.

Just as frost must leave its mark the most distinctly on the coldest of surfaces, so must damp, because the colder these are the greater is the precipitation of moisture on them from the atmosphere. More dew falls on dark soil than on light, and it is the condensation of moisture on Chrysanthemum flowers that causes the least resisting—the thin florets, or those of nominally stouter kinds, but commencing to shrink—though this shrinkage may not be seen—to suffer the first and the most by the visitation. In the case of Mr. Furze the previous cool clear weather had so lowered the temperature of his flowers that when the warm night came, with a moisture-laden atmosphere, his blooms were saturated—gorged beyond endurance—by the condensation of dew on their surfaces, and the weakest, not necessarily the smallest blooms, but more likely the larger, would be the first to fail. Some of the small blooms have stouter florets than the large, and it is in the texture of the florets individually, not the size of the blooms, that we must search for the weakest link in the chain.

As evidence that damping of the blooms of Chrysanthemums is, I

do not say in all, but in many cases, the result of moisture condensing on them, and that this condensation is the result of radiation of heat from the house, and consequently from the plants, I years ago found that when radiation was arrested by the use of blinds on the glass, or, better, elevated a few inches above it, on cold, clear nights, that the keeping of the blooms was prolonged. The idea was suggested by a number of plants in a dry vinery remaining fresh, while others in an equally dry greenhouse damped provokingly. The foliage of the Vines arrested radiation from one house, but there was nothing between the blooms and the glass in the other, at least not until the lesson was learned; then the greenhouse blind used in summer to subdue the rays of the sun was drawn down on cold clear nights in the autumn, radiation was checked, and the blooms then kept as well in one house as the other in after years.

As confirming the soundness of practice—though I think on reflection few will dispute it—I am authoritatively informed that a famous Chrysanthemum grower in the South of England has this year had two vineries filled with plants, the leaves being off the Vines in one house, but on them in the other. The blooms under the Vines have kept fresh, while those under the clear glass only damped, the routine treatment as to watering being the same in both cases. Is it any wonder that he will in future use blinds on the roof on nights when he thinks they will be beneficial? Indeed he has commenced their use, and found the practice good.

Then there is the question of affording light shade from bright sun. This is important, and especially when a cloudless day follows several that have been cloudy. It is under those conditions that Grapes "scald," as it is called. It is not scalding, but shrinkage, the result of sudden and excessive evaporation. It is precisely the same with Chrysanthemums; the florets shrink, many beyond recovery, and those that do not collapse are so weakened that a little precipitation of moisture on them is followed by decay.

The same results follow on the shrinking of the flowers from any cause. If the roots of the plants are injured, as many are, by an over-strong dose of sulphate of ammonia or other powerful fertiliser, the supply of nutriment is necessarily checked, and as a consequence the tenderest part of the plants suffer and shrink first—the flowers. Precisely similar results follow if the roots at any time shrivel from drought, damping following the shrinking if there is any moisture in the air to be condensed on the blooms. For preventing this condensation there are times when brisk fire heat is absolutely essential for Chrysanthemums, and scores of blooms that were lost might have been saved if the houses had not been too cold at a critical time. This was for "keeping the blooms back," and they went back with a vengeance.

Mr. Tunnington of Liverpool stated in one of his practical papers the value of boxes of fresh lime in the house for abstracting moisture from the atmosphere, and some gentlemen at Leicester told me they had tried the plan and found it satisfactory.

There is probably more injury done by overfeeding after the plants are housed than by overdryness, though this must be carefully avoided. I have seen more collections kept too wet than too dry, and the damping of the blooms induced in consequence. I could say more, but dare not in the face of fleeting time, and now commend for your criticism, adverse preferably, my views on this subject, for it is only by opposition and the dissecting of theories that truth can be established; and in connection with this subject I am, as you are, a searcher for truth. The question of sports must perforce remain in abeyance.

ROYAL HORTICULTURAL SOCIETY.

DECEMBER 10TH.

SCIENTIFIC COMMITTEE.—Present: D. Morris, Esq., in the chair, Messrs. MacLachlan, Michael, Church, H. J. Veitch, Pascoe, Rev. W. Wilks, Drs. Müller and Masters.

Hybrid Rhododendron.—Mr. Veitch showed a hybrid Rhododendron between R. Malayanum, a dwarf species, with the backs of the leaves densely scaly, and a hybrid form named Monarch. The new hybrid had luminous, orange-red flowers, and was almost exactly intermediate in all its characteristics between the two parents.

Deformed Carrots.—Mr. Veitch showed a large number of deformed Carrots, in which the crowns, instead of possessing a single central bud, had branched into several, while the ordinarily single tap-root was also branched into several. The roots had been grown on a dry brashy soil in which there were a large number of stones. During the hot dry weather in summer, the soil was so dry and hard that the roots had difficulty in penetrating it, and hence the energy of growth was directed rather to the formation of supernumerary crown buds and root branches than to the ordinary tap-root. Professor Church corroborated the view that the branching of the roots was due to some mechanical obstacle in the soil. He had found the relative quantity of nitrogenous compounds in excess in such roots. Dr. Masters called attention to the presence of a slime fungus in some cases of this kind.

Seakale roots.—Some roots of Seakale, rotten in the centre and affected with fungus, were also exhibited. The Carrots and the Seakale were referred to Professor Marshall Ward for examination and report.

Effect of Fog on Orchid Flowers.—Mr. Veitch showed flowers of Phalaenopsis and Oncidium, showing how the fog affected blossoms which had not fully expanded, and arrested their further development. The specimens were referred to Dr. Scott for examination and report.

Insect Injurious to Sugar-cane in Barbadoes.—This was sent from the botanical station at Barbadoes, and was referred to Mr. Michael.

Production of Seedling Sugar-canes in Barbadoes.—Mention was made of the discovery of seedling Sugar-canes in Barbadoes, and to the interest attaching to them, as furnishing a possible means of obtaining new and improved varieties. It is singular that up to this time the variations in the Sugar-cane have been derived from sports or bud variations.

Dactylopius (Mealy Bug) in Egypt.—Mr. Morris read a letter addressed to the Director, Royal Gardens, Kew, by Mr. R. W. Blunfield:—

"I see in the August number of the *Kew Bulletin* an interesting account of the *Icerya Purchasi*, and its depredations in South Africa, California, &c. During the past four years our gardens at Alexandria have been invaded by a coccus, which threatens now to destroy all our trees, and is causing the greatest alarm here. I have taken the liberty of sending some specimens in a tin box. Our local savants do not seem satisfied as to its scientific name, though one has pronounced it to be the common mealy bug—*C. adonidum*—which I imagine to be a very much smaller insect. It first appeared about four years ago, when I noticed it in quantities on the under side of the leaves of a Banyan tree, but it has since spread with extraordinary rapidity, and one of our most beautiful gardens, full of tropical trees and shrubs, has been almost destroyed. A breeze sends the cottony bugs down in showers in all directions. It seems to attack almost any plant, but the leaves of the *Ficus rubiginosa* and one or two other kinds of Fig seem too tough for it, and it will not touch them. It seems almost hopeless here for a few horticulturists to try to eradicate this formidable pest, while their indifferent neighbours are harbouring hotbeds of it, and there will have to be some strong measures taken by law to put it down."

The insect in question had been referred to Mr. Douglas, and was said to be an undescribed species of *Dactylopius*. Spraying with kerosene emulsion was recommended, but no remedy was likely to be effectual that was not carried out universally.

Excaccaria Fruits.—Mr. Morris exhibited fruit "shells" of this Euphorbiaceous plant received from Formosa, and which were tied together in necklace-like arrangements by silken strands, the work probably of the larva of some moth.

Canker in Apple Tree.—Mr. A. Dean exhibited a branch of Wellington Apple showing a well-marked illustration of canker in a tree grafted on the Crab stock, and planted on a subsoil of clay. The specimen was referred to Professor Marshall Ward for a report.

Action of Frost.—Mr. A. Dean sent a branch of Keddleston Pip-pin, showing the effect of frost in bursting the tissues and cracking the bark. The injury had probably been done some time previously, though only recently observed.

Fruit of Stephanotis.—From Mr. Denning came a seed-pod of this plant, and which is only occasionally produced in cultivation, owing probably to the absence of the insect adapted to fertilise its flowers.

Cone of Pinus Ayacuti.—Dr. Masters showed a fine cone of this Mexican species, grown in the Isle of Man, by Mr. Farrant, and made some comments on the species, which is somewhat tender in the neighbourhood of London.

PARKHALL, STIRLINGSHIRE.

It is not often that when one enters a somewhat obscure place like Parkhall that such a display of glass erection for horticultural purposes meets the gaze, and more than one has been struck with amazement at the immense amount of means applied to the production of fruit, and the success which attends the judicious management of Mr. Murray, Mr. Learmonth's skilful gardener. Passing over a piece of rising ground gigantic ranges meet the view; on the left two large span-roofed houses, 100 feet long, 24 feet wide, and about 16 feet high each are passed, and those who have had the privilege of looking into them during the autumn months have witnessed sights of Grape-growing seldom met with. The kinds grown in these fine structures are chiefly for late supplies. Those most worthy of special mention are unusually fine Gros Marocs. We have seen finer bunches of this kind at Parkhall than anywhere else. Gros Colman (extra fine at present), Gros Guillaume, Alicante, and Mrs. Pearson are also extensively represented—bunches large, many of extra size, and finely finished. The last-named kind is much valued at Parkhall; the quality is rich and refreshing. Fine exhibition Grapes have often been taken from Parkhall, and when the gigantic bunches, so handsome in form, are seen among the competition lots they are easily recognised. The Muscats which have been tabled of late years show fair examples from the general stock of Grapes. Such are not the results of light cropping, as the whole of the Vines are heavily cropped, some of them with about a score of these huge bunches hanging on them. In one of the fine houses referred to there were nearly 1000 bunches hanging. This is only a small portion, however, of the fruit-growing accommodation, as looking further ahead ranges are seen on both sides of the pathway, and the principal one is over 400 feet in length, enclosing three sides of a vegetable garden—wide roomy houses, where Grape growing is finely represented—not on Vines with the insignificant crops of half a dozen bunches, but loaded, as they should be, with three times the quantity one may see on some Vines, and quality of the first rank, while the popular late kinds are well represented. The favourite old Black Hamburg holds a prominent position, and the best Hamburg at the late Caledonian Show held at Edinburgh were from these vineries; but that is not saying much, as what Mr. Muir states is only part of the truth, and most cultivators

which we meet endorse very strongly his remarks. The time was when no other Grapes were supplied to well-appointed tables than Hamburgs (as blacks) up to Christmas, but such is now the exception. At Parkhall many other interesting objects may be seen. The quantities of Peaches, Pears, Plums, &c., grown under glass, and the long low ranges of span-roofed houses for the growth of Cucumbers, Tomatoes, &c., has given Parkhall a name among the leading establishments of the north.

—M. TEMPLE.

COPPER SULPHATE AGAINST FUNGI.

EXPERIENCE during the summer of 1889 encourages the belief that we have in the solutions of copper sulphate a defence against many of the fungus pests which so seriously threaten the prosperity of our agriculture. In 1888 the efficacy of what is known as the Bordeaux mixture as a preventive of mildew and black rot of the Grape was fully proved. This year experiments have taken a wider range, and many of the so-called diseases of plants have been successfully treated. The Apple-leaf rust (*Roestelia pyrata*) succumbs to an occasional spraying with the Bordeaux mixture. The Quince blights (*Morthiera Mespili* and *Hendersonia Cydoniae*) are likewise prevented, and the fungus which causes the blight of leaves and cracking of fruit of the Pear may now be regarded as under the control of the copper solutions.

The prevention of this Pear fungus, *Entomosporium maculatum*, is, perhaps, of greater advantage in the nursery than in the orchard. Where the disease is epidemic in the nursery it places a veto upon the budding and grafting of young Pear stocks. The leaves are destroyed just when their aid is essential to the vitality of the bud or scion. By spraying the nursery rows every three weeks during the season of growth with the Bordeaux mixture the leaves are preserved in health and the success of the grafter's labour is assured.

But in addition to this use of the copper solution it is found to be preventive of the Tomato blight (*Macrosporium Solani*), and (which is of far wider importance to our agriculture) it prevents the rot of the Potato, *Phytophthora infestans*. In treatment of this disease of the Potato plant some of our experiment stations have this year been quite successful. My experiments in this line have had gratifying results. For many years in this region of southern New Jersey every attempt to grow the Peachblow Potato has been a failure. At about the time the plant is in blossom and the tubers are say one-fourth grown, this deadly blight invades the Potato field and sweeps over it like fire. I have had an acre of Peachblows showing every sign of thriftiness and giving promise of a heavy crop, and in one week from the time of the appearance of this blight every plant was dead or dying. It is the prevailing opinion here that the Peachblow Potato is a variety which is "run out," and its culture has been generally abandoned.

Happening to see, last autumn, a few bushels of small Peachblow Potatoes for sale, I bought them for the purpose of giving them another fair trial under the protection of the Bordeaux mixture. Last June I ploughed a Clover sod between the tree-rows of an orchard, and there planted these Potatoes in five equal plats of three rows each, manured in the row with the Mapes Potato manure at the rate of half a ton per acre. The plats lay side by side, running north and south. When the plants were a foot high, and before they blossomed, I began to spray some of them with the Bordeaux mixture, and repeated this operation every two or three weeks thereafter until nearly the last of September. The times of treatments were regulated somewhat by the weather and the frequency of heavy rains. At any rate, I aimed to keep leaves and stalks on the sprayed plats pretty thoroughly white-washed with the copper sulphate solution, so that its presence was always visible all over the plants. Whenever a drenching rain washed off the application it was renewed as soon as possible. I made the treatments with the portable Eureka spraying machine. I thus sprayed plats 1 and 2, left plat 3 (the middle plat) untreated, and sprayed also plats 4 and 5.

About the time the plants blossomed the middle plat (No. 3) was, as usual, struck by the blight, and in two weeks all of the Potato tops on this plat were dead and dry. The plants on the other plats were green, and growing as vigorously as could be wished. They remained green and growing until killed by frost in November.

I then dug and weighed separately the total product of each plat. Plat No. 1, sprayed with Bordeaux mixture, yielded 346 lbs. of fine large marketable Potatoes, which were sold as soon as dug for a dollar a bushel. Plat No. 3, not sprayed, yielded only 164 lbs. of small-sized tubers, scarcely one of which is marketable.

The diameter of the largest tuber on the untreated plat was 3 inches. The diameter of the largest on the treated plat was 5 inches. There is a marked difference in the cooking of Potatoes from the unsprayed and from the sprayed plats. Those from the plat not treated are immature and "soggy." Those from the treated plats are mealy, and have all the excellence for which the Peachblow Potato was formerly esteemed.

I have saved 10 or 15 bushels of these Peachblows to plant next year, in the confident expectation of a crop of 350 bushels of Potatoes per acre. Under the unfavourable conditions in which these experimental plats of Potatoes were grown (between rows of trees 20 feet apart and twenty years old) I did not expect a large crop; yet the yield of the treated plat (No. 1), 346 lbs. from 225 hills, is not bad under the circumstances, being about 125 bushels per acre.

Of the Bordeaux mixture employed the formula is 6 lbs. of pulverised sulphate of copper (blue vitriol), dissolved in four gallons of hot water; 4 lbs. of fresh lime, dissolved in four gallons of cold water; mix the two

solutions, and dilute with cold water to make twenty-two gallons of liquid.

I believe, however, that the ammoniacal solution of carbonate of copper will be found as efficient a fungicide as the Bordeaux mixture, and it has the advantage of being more readily prepared and more easily distributed in spray. Its formula is carbonate of copper, 3 ozs.; ammonia, one quart; mix. The copper carbonate will dissolve almost at once in the ammonia liquor. Then dilute this mixture with cold water to make twenty-two gallons of liquid.

From sundry experiments which I have made this year, and which I have reported in detail to the United States Department of Agriculture, I conclude that it is the copper in solution which is specifically antidotal to fungus germs, and not the other component, sulphuric acid, of the sulphate. In experimenting on treatment of the black rot of the Grape I tried quite extensively a mixture made similarly to the Bordeaux mixture, only substituting sulphate of iron (copperas) for the copper sulphate. This mixture had no effect whatever in prevention of Grape rot. I saw some benefit from its use, however, in prevention of leaf mildew, and it is quite likely that it may be found sufficiently effective for treatment of the blights of the Potato and Tomato. It is much cheaper, pulverised sulphate of copper costing about 8 cents. per lb., while copperas costs only seven-eighths of 1 cent per lb.

Further experiments are required to teach which of these fungicides may be the preferable one, and for what uses. Certain fungi will endure with impunity applications under which others will perish, and certain varieties of plants are damaged by chemical solutions which do not harm others. Thus, the Tomato plant will not tolerate a spraying Bordeaux mixture as it is used for the Potato. The mixture for the Tomato must be reduced in strength at least one-half. Nor will *Vitis æstivalis* endure spraying with copper sulphate mixtures, which do not injure the vegetation of *Vitis Labrusca*.

My counsel to those who purpose engaging in these vegetable therapeutics is to go slow. When all ready for spraying try only a few patients at first, and wait to note the effects of the medicine. Otherwise there is great danger of learning pathological wisdom as did the quack doctor who found out in his practice that "what cured the shoemaker killed the tailor."—A. W. PEARSON, *Vineland, N.J.* (in *American Garden and Forest*).

LIQUORICE (GLYCYRHIZA GLABRA). ITS CULTURE AND USES.

PONTEFRAC and its immediate neighbourhood is probably the only district in the kingdom where this plant is grown to perfection. Liquorice requires a great depth of soil, as the length of the roots, which is the only valuable part of the plant, varies from 3 to 6 feet in length, and I have seen it 9 feet in length.

Pontefract has ever been noted for its rich fertile soil, as well as its pure bracing atmosphere. Fruit and vegetables are produced in abundance, and the excellent quality of both is demonstrated by the ready sale effected at the neighbouring markets. The ingenious Thomas Fuller has styled Pontefract "the garden of England," and the poet Lund, in the early part of the century, expressed himself in the following lines:—

"If situation hath a power to please,
If air salubrious can give us ease,
If spacious streets and handsome houses joined
Can satisfaction raise within the mind;
If noble ruins, mouldering fast with rust,
Where ancient monarchs mingled with the dust;
If gardens all around can please the eye,
Embellished o'er with Flora's painted dye;
If peace and plenty, which doth here abide
(Laying all pique and prejudice aside).
If charms as these are worthy of my song,
Come here ye grave, ye gay, ye old and young—
Come here and view the subject of my theme,
Confess that Pomfret's worthy your esteem."

When the Liquorice plant was first introduced is somewhat uncertain, it having been cultivated for a long period, but never to the extent it is at the present time. There is now a great acreage under cultivation, giving employment to a large number of people. Any approximation to this number would be difficult, inasmuch as during the two first years the spaces between the beds are utilised in growing vegetables, generally early Potatoes the first year and Cabbages the second. The protection of the Liquorice beds enables these crops to come to early maturity; the extreme fertility of the soil, with these advantages, produces a splendid quality. The land for the culture of Liquorice is worked entirely with the spade. After the two first years the Liquorice requires the whole space of the land, inasmuch as it makes too much top to allow of anything else being grown. The fourth year brings it to perfection.

It is planted in raised beds on rows 2 feet apart. Three hundred of these beds constitute a quarter. These quarters are planted

year after year successively, thus each year brings one quarter to maturity. Condition of seasons favourable to the plant:—Should the two first seasons after planting be moderately wet, and the two latter inclined to dryness, the result is so much more satisfactory. The season for planting is the early part of April; the season for taking up or trenching out is from the middle of September onwards.

After the root is taken up it is stored in cool warehouses or cellars in sand, until opportunity offers for dressing. This consists of taking off all small fibrous roots, buds, and runners from the rod. The small fibres are ground up into liquorice powder, and used for medicinal purposes. The buds and runners are then faced and preserved in sand, ready for planting. The rod is pounded by machinery, and the saccharine extract is refined and made into the

FIG. 69.—LIQUORICE (GLYCYRHIZA GLABRA).

celebrated Pomfret cakes. This industry is the staple trade of the good old town of Pontefract.—JOHN HILLARY, JUN.

EUPATORIUMS.

THE notes by Mr. Muir and "W. S." on these plants are quite seasonable. It is, indeed, a wonder that these plants are not more numerous cultivated. There is one objection to the earliest flowering variety which commences in October, and which I have always known by the name of *E. odoratum*—that is, the flowers are a dirty white, which is certainly a blemish. I know ladies object to this simply on account of its colour. Whether or not this is the correct name the flowers answer very well to the name, but although scented it is not of the most agreeable character. For freedom in flowering and the time the plants last in bloom this variety is perhaps the most useful, but for making a greater show I prefer *E. Weinmannianum*, although this comes in at a time when other flowers are more numerous. We have

plants of *E. odoratum* which have supplied us with flowers annually during the last nine years, and they promise to go on as many more.

After flowering is past the current year's shoots are pruned to within one or two eyes of the older wood, the plants are then placed in a cool house for a time; in the spring they are placed into a Peach house, the trees of which are not forced, but allowed to come on quietly. The syringing necessary for the Peach trees suits the *Eupatoriums*, inducing abundance of shoots to be made. When the shoots are 2 inches long the point of each is pinched out to induce additional growths. When all fear of frost is past the plants are stood out of doors in a sunny place, the pots plunged in ashes to lessen the supply of water required at the roots. When the shoots have grown 3 or 4 inches they are clipped with the hedge shears; afterwards they are allowed to grow away at will. The dwarf branching variety referred to by "W. S." I have always known as *E. riparium*; it is the whitest of the three, but owing to its straggling habit is not so useful in a cut state, as the flower spikes are crooked, but as a pot plant it is capital. This has the darkest coloured foliage of all; the stems, too, are dark red.

There is yet another *Eupatorium* not mentioned by either of your correspondents. I allude to *E. Candollei*, which is often called a white *Ageratum*, owing to the flower heads being much like an *Ageratum* in formation. This flowers in March, is pure white, is more bushy in growth than any other sort, and is best raised from cuttings annually in April, pinched three or four times, and flowered in the greenhouse in 6-inch pots.—E. M.

FRUIT FORCING.

FIGS.—*Early Forced Trees in Pots.*—Early Figs are best secured from trees in pots, as a slight warmth at the roots is highly beneficial; but even this has its disadvantages, as when the heat at the roots is 70° or more during the early part of the forcing process the growth is too rapid; therefore see that the heat at the base of the pots is not more than that until the leaves are unfolding, when the temperature may be 75°, or even 80° at the base of the pots. The temperature of the house should be increased gradually to 60° at night, 65° by day by artificial means in severe weather, 5° more in mild weather, 70° to 75° with sun heat and moderate ventilation, closing at 75°; but be careful not to bring on the growth too rapidly, especially in dull weather, as foliage produced under such conditions is not of stout texture, but thin, and liable to be scorched under bright sun. Water in a tepid state must be applied to the roots as required, and the trees and house must be syringed morning and afternoon, the latter early enough to have the foliage dry before nightfall, damping the house later in the day if the atmosphere has become dry.

VINES.—*Early Forced in Pots.*—Attention must be given to the fermenting materials in the pits, and if the pots are placed on pillars frequent additions of material should be made as the heat declines. The heat about the pots must be kept between 70° and 75°. The temperature should have been gradually raised after the buds commenced swelling from 55°, so as to have it about 60° to 65° by the time they are coming into leaf, allowing an advance of 5° to 10° by day, carefully admitting a little air at 70°, and close early. Disbud as soon as the bunches can be detected, reserving the most promising. Stop the shoots about two joints beyond the bunches. The laterals or growths on the current year's wood should be removed up to the bunches, and those beyond allowed to extend as the space permits without crowding, it being essential that the foliage retained have full exposure to light and air, and no more than that encouraged. Usually a couple or three joints of lateral extension are sufficient for fruiting Vines in pots, the crop preventing much further extension. Where fermenting materials are employed the necessity for the application of moisture will not be so great as where the heat is obtained solely from hot-water pipes. Evaporation troughs should be filled with liquid manure or guano water, 1 lb. of guano to twenty gallons of water, which may be employed for damping the floors, &c., after closing the house, or early in the afternoon.

Early Forced House.—The buds of Vines started last month now show signs of swelling, and another good watering should be given the inside border at a temperature of 85° to 90°, and in the case of old Vines apply liquid manure freely. From the time the buds commence swelling raise the temperature 2° or 3° in the course of a few days, not exceeding 60° to 65° by artificial means until the Vines have produced their leaves. In quick forcing and where the Vines are thoroughly established and have had a rest, growth may be induced by a brisk moist heat of 70° to 75°, continuing it until the eyes have fairly started growing, when the temperature should be allowed to fall to 60° to 65° at night, with 5° to 10° rise in the daytime, it being important whilst the foliage is being made that a moderate temperature be employed, in order to secure short-jointed wood and stout well-developed foliage. Young Vines that have not been forced early will need to be brought down to a horizontal position to ensure their breaking regularly.

Some well-fermented short stable litter and leaves placed in ridges on the inside border will afford a genial moisture and warmth, and lessen the necessity for frequent syringing. See that the fermenting material on outside borders are not cooled by snow melting on them, and lose no opportunity of turning and adding fresh material as may be required.

Cherry House.—To ensure a supply of ripe Cherries from the middle of April and onwards houses which are to be employed for that purpose must now be closed. Be sparing of fire heat at the commencement, not employing it unless absolutely necessary to maintain the temperature at from 35° to 40° at night, and 40° to 45° by day, ventilating when the temperature is about 50° to 55°. Close the house at 50°. Syringe the trees and available surfaces early on fine afternoons, so as to admit of the buds becoming dry before nightfall. The border will be sufficiently moist through the removal of the roof lights, if not it must have water to bring it into a thoroughly moist state. Trees in pots if at all dry will require repeated supplies of water to secure the thorough moistening of the soil to the base of the pots.

STRAWBERRIES IN POTS.—*Earliest Forced.*—When the crowns commence swelling and the trusses appear the temperature may be advanced a few degrees by day. A temperature of 50° to 55° at night is sufficiently high for the present. Syringe the plants gently in early parts of fine afternoons, which will be highly advantageous, but avoid a close and very humid atmosphere. Keep a sharp look out for aphides, and if any appear fumigate the house on two or three consecutive calm evenings, having the foliage dry, or at this time of year it may be practised in the evening and again the following morning.

Successional Plants.—More plants may be placed in a house from which frost is excluded, the decayed leaves being removed, and the surface soil loosened and top-dressed with horse droppings rubbed through a sieve. Attend to the drainage, and if necessary renew it, and wash the pots. The plants may be introduced during the next three weeks to a house where forcing is carried on, as that of a Peach house, vinery, or Strawberry house, if such be available. Noble, La Grosse Sucrée, Vicomtesse Hericart de Thury, Sir Joseph Paxton, and President are suitable varieties. Plants for introducing later on will be quite safe in their quarters out of doors plunged in ashes to the rim, and a light covering may be given of dry fern or litter in severe weather, removing it in mild weather.

KITCHEN GARDEN.

FORCING.—This should now be general, and as there are indications of the winter being severe, deficiencies that may occur in open air supplies must be met by forced produce.

CHICORY.—One of the most useful of all winter salad plants for forcing. It is easily managed, and the tender heads it throws up when forced are very valuable. The roots are not unlike white Carrots. The top growths die almost away in November, and if the roots are dug up in December, potted in groups of six, eight, or ten into 9-inch or 10-inch pots, and plunged or placed in a gentle heat in a partially dark place, fine heads of crisp cream-coloured leaves will be produced in a fortnight or so. A warm Mushroom house is a good place to force it in, or if they are placed in a Cucumber pit, and a pot of the same size as that containing the roots is placed upside down over the full ones, the produce will be well blanched. A large number of pots may be filled at once, but if introduced to heat eight or a dozen at a time, a constant succession may be kept up.

RHUBARB.—This may now be forced in the ground where it grows. Some old casks with the bottom removed answer well for protectors. Turn one of these upside down over each crown, bore a hole in the upper end, and surround the cask with a firm bed of fermenting material. If the casks are about 3 feet high make the bed up to the level. Old cases may be used in the same way, only if not more than 2 feet deep the sticks when they push up may be injured by coming in contact with the top. It is still up-hill work to force Seakale in this way, and until the turn of the year the roots should be dug up and forced as previously directed. The five-year-old Asparagus roots we are forcing are proving very remunerative, and a succession should be maintained by putting from twenty to fifty roots in to force every fortnight, or as demand suggests.

KIDNEY BEANS.—Our present plants of these are not very fruitful, as December is one of the worst months in the year, but the time is not far distant when they will give better returns, and as it takes them from nine to ten weeks to get into pod, seed should now be sown for late January and February fruiting plants. These cannot be grown carelessly at the present time, and the only sure way of their succeeding is to sow the seed in 3-inch pots and place them near the glass in a temperature of 65°. Six, eight, or not more than ten seeds may be placed into each pot, using rather strong and rich, but well drained, soil. When the plants are about 6 inches high each potful can be transferred to a 6-inch or 7-inch pot, and from five dozen, or thereabouts, many dishes of Beans will be gathered.

MINT AND TARRAGON.—Where those are valued green at mid-winter a quantity of roots of both may be lifted, potted, and plunged in a bottom heat of 80°. We also place them into cutting boxes, put a little light soil over and under them, and force them in that way, but they do not become ready so soon in the boxes as in the pots. Examine young Cauliflower plants, remove all decayed leaves, and if they are inclined to damp off sprinkle a little sand between them. Cut and store Broccoli as fast as they form, as they will not bear the slightest frost. Protect tender vegetables of all kinds from frost.

THE BEE-KEEPER

QUEEN REARING IN RELATION TO HYBERNATION AND WINTER DYSENTERY.

(Continued from page 497.)

SOME of the plans followed in America are scarcely creditable to such an intelligent nation. Here is a plan advocated in a book by G. M. Doolittle, a great breeder of queens and a "real Yankee," a regular "Down Easter." He gets a number of sticks, soaks them in water, then dips them in melted wax time after time, but each time not quite so much as previously. When done enough he fixes their ends to flat sticks, and when cold he can withdraw the round sticks he has used as moulds, as, being wet, they will leave the wax. The flat stick is filled with these cups, side by side; then he puts in each a little royal jelly that he has previously collected from queen cells, and a just hatched worker larva, then these sticks are fastened in frames, and hung in a stock that is inclined to build queen cells, preferring one with the swarming fever on. The bees feed the worms and finish off the cells, and when sealed he removes them, cuts off the cells, giving them either to nuclei, or hatching them in a nursery. And he thinks by doing this he is improving the breed of bees. If his time at the busiest part of the season is of no more value than that of bees, that he can seriously hope to compete with them, where the price of labour is admitted to be high, I think we cannot do better than flock over to America. This reminds me of an anecdote I saw the other day, where down in one of the Southern States they had replaced mules on the tramway with motive power, when an old negro exclaimed, "What a wonderful people those Yankees were! Twenty-five years ago they freed the nigger, and now they have freed the mule." It is certainly reserved for a Yankee to seriously try to free the bees of their natural labour by substituting their own.

Whether Doolittle succeeds or not in his queen-rearing may be judged by his losing on an average about half of his bees every winter; then he selects the best in the spring, sometimes only ten stocks out of a hundred he had in the fall, which he devotes to honey getting, all the weak and sickly ones being devoted to rearing queens; he probably makes his stocks up to 100 again in the fall. Instead, however, of estimating his honey crop *pro rata*, according to the number of stocks he had in the fall, he simply does so on the few best he has selected, which enables him to boast of an enormous crop of honey of an average amount per colony, spring count—not the ten hives, mind, but all their increase, which is seldom less than 100 lbs. "per colony." According to his own showing it is really less than 10 lbs. per stock, while I have made the crop to be less than 2 lbs., and nearly every stock required 10 to 20 lbs. of food to winter it, while all the time he was boasting of "75 lbs. per colony." Such statements do to puzzle people who cannot think for themselves; but the most curious part of the matter is Doolittle is always advocating a strict adherence to Nature, though the only natural plan he follows is rearing his queens in stocks with the swarming fever on. In my opinion the reason he does not lose all his bees every winter is because his frames being 11½ inches square he always has his brood nest in a close compact shape, so that the cells do not run such a risk of chilling if cold weather sets in as they would if he used the Langstroth frame. This again is not without its influence in enabling him to harvest large crops of honey from those hives he selects for the purpose.

It was Heddou who started the "pollen theory" to account for winter dysentery, just because he ascertained that such bees voided undigested pollen. To prove his position he fed a number of stocks up for winter on pure sugar syrup in clean combs devoid of pollen, which lived through the winter and came out satisfactorily in the spring, while many of those with pollen in their combs died. He held this up as absolute proof, though a little reflection should

have told him that he only provided his bees with a more digestible food.

To understand this subject better my articles in the Journal for May 16th (page 407) and July 18th, 1889, must be read as well as this. I cannot yet say if bees keep up one uniform temperature in the cluster while hibernating in winter or not, though I think they do; nor what that temperature is, which I think is about 60°. My bees are all now hibernating except one stock with the queen developed from a fertile worker egg which received a slight chill while in the cell, and was otherwise not reared as well as my other queens.

To sum the matter up briefly, I advise the following course—breed queens from the best stocks. Let them be reared naturally whether under the swarming fever or not. Never open a hive to look at cells being reared, nor think of cutting one out. If the selected stock swarms catch the old queen, or let all or nearly all the bees go back to attend to the maturing cells, always remembering that Nature has designed them to be kept quite warm, so that there can never be too many bees in the hive. They will come outside if no room within. If the weather changes to cold, wet, or otherwise bad feed at once gently and continuously until it takes up again, to cause the bees to keep up the heat of the hive, otherwise they would let it go down too low, and thus spoil all the queen cells. If young queens are wanted keep taking them in the swarms, and let the bees go back, to come off again with fresh ones. If many queens are wanted rear them under the swarming fever, when you will have from ten to 100. If you only want one you can rear her in any very strong stock, but be content with one, as seldom will there be more than two cells, and you cannot cut one out without spoiling both. If you wish the bees to be profitable take care that they have sound constitutions, always remembering that such will enable them to withstand all kinds of failings in management and the weather. And always remember that the queen is the most important part of a hive of bees, and must always be considered the most valuable part.

I may also touch on the question of clipping queens' wings. I used to be opposed to the practice, as I found bees had such a desire to supersede them. I have again reverted to it, as I can thus catch the old queen in a first swarm, and soon have the bees back again; while if I am not present, and the hive is on a stand that overlaps, so that the queen cannot get back, she will be found on the ground under the entrance, as she is attracted by noise of the returning bees, and tries to get back. Another point is, if you clip a queen as soon as she begins to lay you can always tell if she has been superseded, which often happens when the stock is not as strong as desirable for queen rearing, so that such queens should be replaced. Thus, although clipping has several drawbacks it also has its advantages when rearing improved bees.

I have now explained the matter, and if it is followed it will not be long before a marked difference will be noted between the bees as now existing, and those being cultivated, and which will soon be known as "wild bees." Of course there is the difficulty about the drones; if each bee-keeper will breed these as he is advised about his queens, there will not, however, be much trouble on this score.—A HALLAMSHIRE BEE-KEEPER.

GLASS SECTIONS.

ALLOW me to tender my best thanks to "A Hallamshire Bee-keeper" for his brief and practical exposition of the patent laws; also for the trouble he had been at in preparing drawings to illustrate the making of glass sections, which doubtless would have been published but for the good reason indicated. If ever I had a serious intention of cheating the inventor of the metal corners by "any quibble or sophistry," the idea had vanished from my mind before I knew so much of patent laws as I now do. While the note I sent to the Journal was lying at the office waiting for a corner, I have been working and thinking, and have come to much the same conclusion as your correspondent—viz., that they are quite as well without the tin corners. I hope "A. H. B. K." does not include me amongst those who say they "knew the dodge before," or who laughed at him. My motive was a desire to

learn, and I hope the same was shared by most bee-keeping readers of this Journal. I may say that I have found what "A. H. B. K." told last year quite correct as to the cost of glass. I can make them from glass cut into squares for glazing purposes at less than 3s. per 100. I make them as a pastime, and for this new pleasure in bee-keeping your correspondent has the best thanks of—A SUSSEX AMATEUR.

TRADE CATALOGUES RECEIVED.

Ewing & Co., Havant.—*List of Nursery Stock and Roses.*
 J. Cocker & Sons, Aberdeen.—*Catalogues of Bulbs and Roses.*
 Bruant, Poitiers, Vienne, France.—*General Catalogue.*

* All correspondence should be directed either to "THE EDITOR" or to "THE PUBLISHER." Letters addressed to Dr. Hogg or members of the staff often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post, and we do not undertake to return rejected communications.

Coloured Potatoes (Cottager).—The Dean and Vicar of Laleham are good round, and Mr. Bresee and Edgcott Purple good kidney varieties, both for exhibition and table use.

Eucharis Flowers (A. S., and C. F.).—We frequently see examples of Eucharis flowers with more than the normal number of petals exactly like yours. It is a tendency to the double condition, and is probably due to the strength of the plants.

Painting Hot-water Pipes (H. C.).—It is not necessary to add anything to the lampblack and boiled linseed oil for the purpose. Choose a suitable day when the pipes can be gently heated and the ventilators opened if you have plants in the house.

Phalænopsis amabilis and Calanthe Veitchi (C. L., Bristol, and J. P., Beaconsfield).—A Phalænopsis panicle 4 feet 7 inches long with twenty-nine flowers is fine, and the plant is well treated. The Calanthe with a pseudo-bulb 11 inches long and a spike 4 feet 5 inches high must have been strongly grown. It is very good.

Horn and Hoof Shavings for Vine Border (J. B.).—They are excellent for mixing with loam for a Vine border, and if you add also some road ashes, you will have a very suitable compost. Horn contains phosphate and sulphate of lime with phosphate of magnesia, and differs from bones in containing a considerable proportion of sulphur. Horn and hoof parings form a somewhat more powerful manure than bones, and are lasting in effect, through the slow decomposition of the matter in them, which appears to be of the nature of coagulated albumen.

Emigrating (R. H.).—Unless you have friends in the colony who would tender you some assistance in the form of hospitality and advice, we should consider the sum you name inadequate to start with, though we have no doubt many persons have started with less, and after struggling with adversity and enduring privations at which they would seriously grumble at home, have eventually "done well." In an article on another page you will find remarks on the subject, and addresses from which you can gain information that may possibly be of service to you under the circumstances.

Peach Tree Buds Falling (Zero).—The letter to which you refer did not reach us. The buds fall from the trees from various causes, such as drought at the roots at some time anterior to the misfortune occurring, red spider on the foliage in summer, a sudden change of treatment from full exposure to a close house, a paucity of active fibrous roots in good soil, also through overcropping. There is nothing in your letter to suggest to which of those causes the evil is due in your case. You may have excited the tree too soon and too suddenly. If you like to send a sample of the wood, and give more particulars as to the age of the tree, also state when it was lifted and started, with the temperature maintained, we shall be glad to give the case further consideration. Several letters fail to reach us through being incorrectly or insufficiently addressed.

What is a Good Crop of Tomatoes (S. S.).—You ask "What is a fair good crop of Tomatoes in pounds weight per plant when the plants are grown to a single stem upright to a height of 12 feet, and under glass, planted out as strong sturdy plants out of single 5-inch pots at the beginning of June—that is, what should fairly be expected under such circumstances?" Though we know that 20 lbs. of fruit, and occasionally more, have been gathered from each of a number of plants grown as suggested, the weight, we suspect, exceeds the average. This, according to the Chiswick results with several hundreds of plants, is about 15 lbs. They were, however, planted in the best of condition about a month sooner than yours, and grown practically without fire heat, though a little may have been employed for ripening the later fruits in the autumn. We shall be glad to have the experience of other cultivators on the weight of their Tomato crops.

Keeping Pears (E. F.).—Mr. Bardney writes:—"We are careful to gather the fruit perfectly dry and store it at once as the work of gathering proceeds. If we use the large boxes to which I referred another year we shall take them to the tree and pack them as the fruit is gathered. We find that, although the paper in which the fruit was packed, and the paper shavings become damp, when such large boxes as I described are filled, no harm appears to result to the fruit. But we prefer the smaller boxes, and then the dampness is not so perceptible. I have not tried the sand, and therefore really cannot say whether it is better than the paper shavings or not. It is worth trying, however. I have been thinking lately about cork dust, such as is used for packing Grapes and Tomatoes. I saw quantities of the latter this season sent from Teneriffe that arrived in excellent condition, and are likely to considerably reduce the price of home grown produce early in the season."

Plumbago capensis to Flower in August (M. N.).—The plant should be kept cool and dry, but not so dry as to cause the wood to shrivel, until early April, when it should be pruned, and having the ball reduced about a third be repotted. Growth may be encouraged by syringing, but the moisture at the roots must be moderate until the roots are working freely in the fresh soil, when it will be required more freely, and when the pot is filled with roots afford liquid manure once or twice a week. The plants may be started in ainery or Peach house, and after some little growth is made it will be best given a light airy position in a greenhouse or conservatory. Its free flowering depends on the ripening of the wood. If that is strong, short-jointed, and firm it will flower freely enough. It should flower about the time you require, but plants for special purposes require judgment in keeping it cool if too early, or placing in heat if not sufficiently advanced.

Lime for Plum Trees—Varieties of Fruit (Plum).—We cannot possibly tell you whether a "couple of shovelfuls" of lime would suffice for each tree, as you give no indication whatever respecting either age or size. Cut out the cankered parts as you suggest and spread lime half an inch thick as far as the roots extend, then mulch as you propose with good manure. But it is useless placing fertilising material close to the stems of trees alone where there are few fibrous roots; the best of these are some distance away, and support should be applied where it can be appropriated. All the varieties of fruit you send are good, but only three out of the eleven Apples are spelt correctly, and if we were to print the names as you have sent them they would cause some amusement. We give one as a sample—"Ecklinvil" for Ecklinville. Before attaching names to the trees you had better consult a fruit catalogue, and not attempt to improve on the names you find in it. The Blenheim Pippin is a fine Apple, but somewhat slow in bearing freely, and Golden Noble is not very quick in that respect, but when they do bear well they are profitable.

Fruit in Boxes (St. Julian).—See Mr. Bardney's reply to another correspondent. Paper shavings are the trimmings of paper that are plentiful in printing and bookbinding establishments, and cost little. The boxes will do if the lids are tied down tightly, but ordinary fastenings or even tacking are better and more quickly applied. Both Apples and Pears will do in the same room, and both keep well in sweet boxes or barrels without any packing, and many of them better so than on shelves. The time for examining fruit in boxes and introducing to heat for ripening depends on the varieties and the supply required. When paper other than shavings is used any that is thin, white, and cheap is suitable. We do not approve of old newspapers, as some of the ink employed in printing impairs the quality of the fruit. The choicest samples are wrapped in paper by some persons, who find the plan satisfactory; others place the fruit in alternate layers with paper, but by far the greater bulk is packed in barrels without anything, but we repeat they must be sweet. See Mr. Wright's work on "Profitable Fruit Growing," price 1s.; post free from this office, 1s. 3d. The subject of storing fruit will perhaps be alluded to again.

Galls on Gardenias (R. S.).—The galls upon the roots sent appear to be the abodes of a mite, one of those which, unlike most of its brethren, goes through distinct transformation. These are at present in the nymph condition, but would develop fully in spring, and then proceed to scatter themselves and propagate; but their history is at present very obscure, and they generally are so sluggish that their travelling about seems unlikely, yet this must occur when fresh galls are produced. It is a species belonging to the genus *Tyroglyphus*; this, or one closely allied to it, has been taken in galls upon Vine roots, which has been erroneously attributed to *phylloxera*. Another *Tyroglyphus* frequently infests Mushrooms. So little is as yet known about these creatures, even amongst entomologists, that it is difficult to suggest remedial measures. We should consider the advisability of raising plants from a clean stock, and grow them in soil that has been subjected to a roasting process. The infested plants, also the soil in which they are established, we should consign to the fire, as according to your description of them they are unsightly and may be expected to get worse. You might experiment on one or two of them with a rather strong petroleum mixture, commencing with a wineglassful of the oil briskly stirred in a gallon of soft water; it may possibly, however, require a stronger dose to destroy the encased enemy than will be good for the plants, and we suspect the stamping out process will have to be resorted to sooner or later.

Applying Liquid Manure to Vine Borders (Inquirer).—1, Provided the borders are well drained you may safely and advantageously water them with the liquid from the farmyard, as the superfluous moisture will be carried off, the water being displaced by the liquid to a great extent through its being more fluid, the manurial matter being absorbed and retained. There is reason, however, even in applying liquid manure, as to afford it too abundantly may cause the soil to become sodden or sour, and then it had better never have been applied. One or two good soakings before starting the Vines is in most instances all that is desirable. After growth is made give a good supply, also after the Grapes are set, and when they are commencing to colour or have stoned. 2, We have tried cutting off the aerial roots on Vine rods and allowing them to remain, and found no material advantage either way. Aerial roots are evidence of too close and moist atmosphere with a slow or defective root action. They are very common with Vines that have their roots in cold and unprotected outside borders, and never (at least in our experience) appear on Vines that have the roots in a satisfactory condition, through the soil and border being in good condition, and have a temperature corresponding to that of the atmosphere, so as to induce reciprocity of action between the feeders and elaborating organs—i.e., the leaves. 3, Some use surface dressings of fresh cow dung, 2 or 3 inches depth, and with very satisfactory results, but we have not heard of the practice you describe before, and certainly should not consider it a desirable one; but, on the contrary, likely to do more harm than good.

Names of Fruits.—The names and addresses of senders of fruit to be named must in all cases be enclosed with the specimens, whether letters referring to the fruit are sent by post or not. The names are not necessarily required for publication, initials sufficing for that. Only six specimens can be named at once, and any beyond that number cannot be preserved. (*Miss Carver*).—1, Waltham Abbey Seedling; 2, Round Winter Nonesuch; 3, Winter Colman; 4, Waltham Abbey Seedling; 5, Royal Russet. (*W. B. Milford*).—Dredge's Fame. (*G. Fulford*).—1, Vicar of Winkfield; 2, Waltham Abbey Seedling; 3, Golden Winter Pearmain; 4, Adams' Pearmain; 5, Not known, inferior; 6, Forge. (*H. P.*).—1, Golden Reinette; 2, Winter Greening; 3, Sturmer Pippin. Pears entirely rotten. (*W. B.*).—2, Royal Russet; 4, Rymmer; 6, Winter Pearmain, also known as Duck's Bill. The paper box was smashed in the transit, and the numbers on the other fruits were displaced.

COVENT GARDEN MARKET.—DECEMBER 18TH.

For Christmas decorations cut Evergreens plentiful; Mistletoe, well-berried, plentiful. Holly very scarce of berries.

SWINE.

SIMPLE as the correct management of swine is, blunders constantly occur from carelessness more than anything else. Some pigs are required; they are purchased or bred without any particular attention being given to the special purpose for which they are required, yet selection and careful breeding answer as well in this as in anything else. Why is it that such high prices are paid for special strains of certain breeds? Simply because of care in the breeding and selection of animals decidedly superior to others both for special and general purposes.

To be more particular, and, therefore, more useful, let us take the class of pigs required for use at the home farm. We want a compact animal of chubby tendency that will fatten quickly and is ready for use all through the "porker" stage of its existence, or which may be kept on profitably for home use a few weeks after it has passed that stage. Any surplus of such pigs always commands a ready market in all towns, and they are sold as "Londoners" at long distances from the metropolis, where they are in constant request at the Central Meat Market. Farmers are loud in complaints of high railway rates, yet we are bound to admit that we have for several years had porkers regularly killed, dressed, and sent by rail to London from a farm upwards of eighty miles at a profit; not always to our entire satisfaction, for markets fluctuate, and one has to take an average price in making calculations or striking a balance.

A useful class at agricultural shows is that of sows with pigs, as showing the best pigs for our purpose; classes for porkers are also useful, very much more so than that for huge fat hogs. At the recent Smithfield Club Show middle white and black Suffolks were seen to advantage, but nobody could judge of the real value of Tamworths from the specimens shown there. If it be true that porkers of this breed are of especial value because they become

quickly ready for market without the development of an undue proportion of fat, then we hold that in the Agricultural Hall, Islington, of all places, this useful trait should be brought clearly before the public. We saw Tamworths in large numbers with other breeds at several farms in the midlands a short time ago, and had reason to like their appearance. They appear to form a useful mean between the chubby small white and the huge large framed nondescripts to be met with everywhere. We are just now about to stock a small home farm with pigs, and are trying to obtain sows from a friend who has an excellent cross breed between the Suffolk and Berkshire, and a young boar of a good middle white breed. We have had some of these sows at two off-hand farms specially for breeding Londoners, and they have answered admirably, but we approve of an occasional change as tending to promote health and vigour.

Sows certainly repay well for careful selection and sensible treatment. The state of semi-starvation which they are frequently kept after the pigs are weaned is clearly a mistake; a fair healthy condition is always best if we would have good litters of pigs. A breeding sow should always be young and active, and never of very large size. When they become at all heavy and unwieldy they are at once fattened and sold. Large-framed old sows may be made worth £10 or £12, but the meat is coarse grained, and though the huge hams have a noble appearance they are to be avoided. Experience has shown that in profitable pig keeping sows past being useful for breeding are, when fattened, not worth more than about £5 at market. The dealer makes a profit on that price, which it would hardly answer the home farmer's purpose to strive for. The animals have served their turn, and the sooner they can be disposed of at a profit upon the fattening the better for him.

Mention was made last week of the passage inside of and at the back of the breeding sties. We regard this as an important adjunct to the buildings, as we altogether disapprove of any disturbance of the sow in farrowing. It may be necessary to remove teeth from the mouths of the pigs if they lacerate the teats and render the sow savage. Apart from this, there can be no real occasion to touch the pigs for the first month. As soon as the pigs are able to feed they have pollard mixed with milk in a long low trough placed outside the pound, to which they have access through holes closed with slip boards. This is done upon the principle of the speedy development and prompt use or sale, which applies to all animals of the farm. Milk is mentioned for porkers' food, as it is taken for granted that dairy and pig farming are carried on conjointly at every home farm. Meal or pollard mixed with water is nutritious food, but milk and meal is very much more so. The sort of meal used is not so important as that it is pure and wholesome, a mixture being preferable, all inferior grain being so turned to account. It is worthy the attention of home farmers if it is not altogether best to have power and grinding apparatus at the farm rather than have to pay a miller 1s. a sack for the grinding.

WORK ON THE HOME FARM.

Ploughing arrears on heavy land should now be left till spring on every farm where it has been found that the soil suffers from being turned over when wet. This should act as an incentive to early autumn culture before all things, and it was this which caused us to get so forward with our heavy land ploughing as to be able to begin Wheat sowing early in September. The bailiff of that farm had reason to feel proud of his Wheat plant after the wet October when hardly any of the neighbouring farmers had sown any of their winter corn. Not always have we been so successful at seed time, for our Winter Beans were a failure there last autumn. This year they were sown early and sown well, and there is a full plant.

Plenty of Wheat has now been threshed to afford ample supplies of straw for thatching. With several hundreds of old thatched buildings, we have avoided using thatch for any new ones. The general rule that the tenant supplies straw and the landlord labour for repairing old thatch on farm buildings seems fair enough; but it often proves a heavy tax upon tenants of small farms, and we prefer to use some more durable material for new buildings, preferably corrugated tiles as being substantial, cheap, and neat in appearance. Not unfrequently when farms change hands, the entire cost of thatching falls upon the landlord, and it should be the agent's particular care to see that the

work done is thorough and not mere patchwork. When the thatch of a barn has become thin, the only safe course is to cover the whole of it in a substantial manner, and to have an extra thickness upon the ridge. The matter is then out of hand, and the cost is not at all doubtful, as the work is done by the square of 100 feet at a fixed price.

Of almost equal importance to yard drains are troughs for the eaves of the buildings to carry the water to large down pipes into drains away from the yard. Where this is neglected the litter becomes saturated, and frequently enough water falls to wash all manurial constituents out of it. The best remedy for this is covered yards, but needy landlords can hardly afford such luxuries for tenants' cattle now, and it is better to ask for what is possible. For thatch, a cheap and useful gutter is easily contrived with a couple of boards nailed together at right angles, with a cross brace or two and some angle irons, with a little pitch run along the bottom to prevent drip.

MILK FEVER IN COWS.

BELIEVING as I do that any information would be acceptable which will enable cowkeepers to cope more successfully with that dreaded disease in cattle, milk fever, I desire, with your permission, to place before the readers of this Journal a most excellent remedy, discovered by Professor D. McIntosh, who has given much attention to the subject, and used very successfully by Mr. F. A. Cooper of Westbury Court Farm, Bristol.

Prescription.—As soon as possible after it is known that the animal is attacked give (for a large cow) 1½ lb. of Epsom salts, with 1 oz. of powdered ginger in half a gallon of cold water. Mix 1½ lb. of Mustard in warm water, and rub over loins and along the spine, also a little behind the poll. Cover up with sacks and keep warm. Aromatic ammonia, 10 ozs.; spirits of nitrous ether, 20 ozs., mixed. Dose.—3 ozs. in half a pint of cold water every half hour for five doses, then once every hour till the rest is administered. Keep the cow's head up with bundles of straw. No gruel, &c., to be given till she gets up. The quantity of ammonia and ether stated above was, I suppose, considered by the Professor to be sufficient, and probably is so in some cases. The following instance, related to me by Mr. Cooper, will, I think, show that it is not in all. The last dose was given about midnight. Before the morning a relapse had taken place, and by six o'clock the cow was insensible, and of course unable to swallow. He obtained a fresh supply as soon as possible, and frequently moistened her mouth with a little, and also caused her to inhale the fumes. She soon revived, after which the usual doses were administered, amounting to about half the prescribed quantity. About 10 A.M. he had the satisfaction of seeing her rise, and eventually recover.

Another case which goes to prove the same thing was that of a short-horn under my charge. About two hours after the last of the medicine had been given her she evidently showed indication of a relapse. Acting on the experience gained in the last case, Mr. Cooper advised the medicine to be continued in full or half doses according to the state of the patient. The advice proved to be sound, for in a few hours she was standing up, and the next day appeared but little the worse. The milk should not be allowed to accumulate in the udder.—THOMAS SMITH, *Henbury Hill*.

AGRICULTURISTS' POCKET BOOK.—Messrs. Ballière, Tindall & Co. send us a specimen of their Agriculturists' Pocket Book and Diary, which has been compiled for the use of farmers, land agents, and agricultural students. It is a handy and useful companion for all who are connected with the management of land and stock. It has been prepared by Mr. G. E. Bennett, F.R.C.V.S., and is said to be the first work of the kind published in this country, and is based on the German model. It contains valuable tables on the cost of different kinds of work, information on chemical manures, seeds, stock, insects, fungi, and various other matters, with an almanac and diary.

REMARKS.

8th.—Fine and clear, with sunshine during the morning.
9th.—R. in from 1 A.M. to 8.30 A.M., fine day, slight drizzle about 5.30 P.M.; much warmer.
10th.—Mild fair morning, fine afternoon, bright night.
11th.—Fine and bright.
12th.—Fine and sunshiny.
13th.—Dull and drizzly morning, sunshine in afternoon, slight fog in evening.
14th.—Dull and raw.
A damp dull week on the whole, and considerably warmer than the previous one.—
G. J. SIMONS.

CERTAIN seasons of the year are periods of special activity in Covent Garden Market, the great central depôt of vegetable produce in the market, but at no time are the supplies so extensive and the business so great as in the week preceding Christmas. A market morning then presents an astounding spectacle, and familiar as the visitor may be with the enormous population of London, he might think they were preparing for a siege instead of a day's consumption. Yet this is really only a portion of the supplies, for at several other large markets—notably the Borough, near London Bridge—a similar plethora prevails, the S.E., S., and S.W. districts depending to a considerable extent upon this depôt. Covent Garden is, however, thoroughly representative both in the variety of its supplies and in their quality. Its history is closely connected with the development of commercial horticulture, and its records would convey a better idea of the progress made within the present century than those of any existing institution. Probably at no other market in the world can such a wonderful diversity of vegetable products be seen. It is a vast museum of special interest to horticulturists of all kinds, and scarcely less so to the general observer and student. With the growth of the population and the increased demand for fruit, flowers, and vegetables the market has extended its accommodation and resources—not perhaps always so quickly as desirable, but the improvement has come at last if tardily, and it is now in a more efficient condition than at any past period.

An indication is afforded of the change that has taken place in this market by a comparison of the two illustrations on pages 554 and 555. One of these was prepared from a painting by Joseph Vanaken, in the possession of the Marquis of Bute, and depicts the condition of the market in 1745, long before it was covered in, a series of sheds and stalls such as are still seen in provincial towns occupying the space on market days. On other days it is said the market was the scene of many football contests and other sports. The second illustration (fig. 72) represents a portion of what our artist saw in the respective departments a few days before Christmas, 1889, and it is to this we wish now to direct more particular attention, giving a brief review of the leading features and the supplies. To deal with them exhaustively would far exceed our purpose and the space at command.

Commencing with the flower market, which forms the central subject of the illustration, it must be premised that December is not the best month for seeing this department, as notwithstanding the demand it is impossible to secure the variety and abundance of floral attractions that are readily secured in the spring months; still we find every one of the hundreds of stands filled with choice productions, either plants or cut flowers, that cannot fail to excite a feeling of surprise at this time of year. Around London many acres of glass houses are solely devoted to the culture of plants for this market, and it may be easily imagined that special efforts are made to render the Christmas supplies as satisfactory as possible. The bare enumeration of the plants in pots would fill much space, but we can only note a few of the principal features, and amongst them Heaths will rank nearly foremost. Superbly vigorous little specimens, such apparently as only market growers know how to grow, are seen in thousands, *Erica hyemalis* and *E. gracilis autumnalis* almost exclusively, as even as if turned out of a mould,

and all in small pots. Groups, banks, and stages of these plants prove how popular they are, and what a demand exists for them. Fine bushy specimens of white Marguerites (*Chrysanthemum frutescens*) have been noticeable on several stands recently, in striking contrast to these being the brilliant heads of Poinsettias, furnishing the richest colour at the present season. Cartloads and vanloads of Chinese Primulas and Cyclamens have been brought into the market, and speedily transferred to the retailers or decorators who employ such plants in large numbers, and are compelled to resort frequently to Covent Garden to maintain their supply. A few *Richardia* plants are seen, but the spathes are mostly sold separately, and the same may be said of the Poinsettias, which therefore come more strictly under cut flowers. Bulbs and similar forced plants are contributed largely, Hyacinths being perhaps the least satisfactory at this early date, though they are appreciated by many for their fragrance. In effectiveness the early Tulips are far the best, and we have them in three colours—scarlet, yellow, and white, the two first being very popular and cheap. The majority of these are sent up in shallow boxes, in which the bulbs have been closely packed, so that from eighteen to twenty-four are contained in a small space. These are often transferred by the retail florists into pots with Ferns and Lilies of the Valley, and very bright little specimens they make, half a dozen or more in a pot, either of single colours or mixed. A few pots of Mignonette find a place in the stalls, but the Christmas stock of this plant is restricted. The red-berried *Solanum capsicastrum* may perhaps be included here, as the brightly coloured fruits render it as attractive as many of the flowering plants. It is a great favourite, and in good demand now, when colour effects are so much needed.

The great bulk of the plant supplies for Christmas consists, however, of those grown mainly for their foliage, and of proved excellence for decorative purposes, both in regard to grace of habit or distinctness of leaf colouring, or for properties of endurance. Plants of this character are sent in by hundreds of thousands, Ferns, Palms, *Dracenas*, *Aspidistras*, *Ficus*, *Cyperus*, and small *Thuas*, with Laurels, Aucubas, and many other similar plants. In the left hand corner of the illustration one of the special foliage plant stalls is depicted, which on the occasion of our visit was very notable for the effective display of *Dracenas*. It is where a well-known horticulturist, Mr. Bause, now in the market trade, on his own account disposes of the plants he has done so much to improve and grows so well. Prominent amongst the varieties were *Elizabethæ*, *norwoodensis*, *pendula*, *terminalis*, *alba*, *igneæ*, and *Liudeni*. The upper part of the stall was occupied with Palms, *Kentias*, *Latanias*, and *Coccos*, while at the lower part were the much-enduring green and variegated *Aspidistras*. These are fairly representative of the general supplies of foliage plants, the Ferns already mentioned comprising *Pterises* in a large majority, with, however, a good number of the glaucous *Polypodium aureum*. The plant trade is an important one to home growers, as the foreign element does not interfere with it as it does with other departments.

Highly important too is the cut flower department, and the enormous quantities brought in and disposed of during the past few days are astounding. Elaborate series of figures and statistics are often given with regard to market supplies, but they are frequently extremely misleading, founded on imperfect estimates, or simply guesses. An early morning visit to the market itself, attendance at a few of the auction sales of imported produce, or a journey to one of the large market establishments around London, would give a far more reliable idea upon the matter than all the statistics published. For the Christmas market the principal cut flowers are the following, and it may be remarked that a formidable competition is afforded by the continental consignments which arrive in large numbers and are often preferred by purchasers. We recently saw an instance in the case of *Safrano Rose*, of which both foreign and home samples were submitted, but the former were preferred

because retail florists find they command a more ready sale and at a higher price, owing to their better colour and firmer texture. Other Roses are also fairly numerous. Chrysanthemums are still in much request and abundant supply, white incurved and Japanese predominating, but yellow and bronze Japanese are also in demand. Christmas Roses (*Hellebores*), Violets, *Bouvardias*, Lily of the Valley, *Pelargoniums*, *Azaleas*, *Eucharis*, *Gardenias*, *Tuberoses*, double *Primulas*, *Carnations*, Roman *Hyacinths*, and Paper White *Narciss*, *Mignonette*, *Orchids* (*Dendrobiums*, *Odontoglossums*, *Cypripediums*, *Lælias*, and *Zygopetalums* chiefly) are the principal flowers, and some of these are seen in very large quantities; but *Poinsettia* heads are much valued, and sell at as much as 1s. 6d. or 2s. each. They are used rather extensively for table decoration, and large orders are received for them. They require very careful packing, however, a piece of cotton wool being usually placed in the centre of the head, and the bracts tied upwards over this, and surrounded by a large piece of wool to prevent the bracts being damaged. A number of heads can then be packed closely together in small compass, and keep well. It is common to dip the ends of the stems in hot water to prevent the milky sap oozing out, but another method has been found a good one—namely, searing the ends of the stem with a hot iron.

In the florists' shops of the central avenue are found some of the most tasteful combinations of the flowers at command imaginable—bouquets, wreaths, buttonholes, sprays, baskets, crosses, in fact every form in which flowers are employed. Many an excellent lesson may there be learned in the art of floral decoration, as the most experienced hands are constantly engaged upon the work, and the taste of the great refined has to be studied. The left hand corner sketch shows a portion of one of the shops (Mr. Dickson's). White flowers are largely used for the various purposes at this season, and Christmas Roses are in great favour for wreaths and crosses. A soft grey lichen is a favourite just now as the base, and very beautiful the *Hellebore* or *Eucharis* flowers look upon this with a little foliage. Dark Roses are also in much demand for buttonholes, but never too abundant. Violets, however, make up for any deficiency, and *Bouvardias* furnish some useful colour for bouquets and sprays.

A small treatise could be written upon the Christmas fruit supplies, for this department is a scene of special activity. The spacious Floral Hall is now devoted almost exclusively to the auction sales of fruit, and there during the past week have been huge piles of barrels and boxes of all descriptions containing Pears from France; Apples from America; Pine Apples, Bananas, and Oranges from various regions. The Pears merely come in shallow boxes and are nearly all labelled "*Doyenné*" and "*Duchesse*," but the varieties are occasionally somewhat mixed. The American and Canadian Apple barrels are now familiar objects, and many thousands of these have changed hands within the past few days. Newtown Pippins are in most demand, but Baldwins are the most abundant, cheaper, and are liked by many for their colour. It is strange to note in passing through the other market how few good samples of English Apples are seen; these, however, fetch substantial prices. The Pine Apples arrive in boxes somewhat like Orange cases; they are cut with a good stem attached, the crown and this being secured to cross pieces, so that the fruit is kept steady in one position. Cheap Pine Apples are now one of the features of the market, for grand fruits can be purchased for 6s. or 7s., as good as English grown samples that only a few years ago realised 30s. each at Christmas time, and good fruits can be had as low as 3s. In Madeira and neighbouring islands Pine Apple culture has been greatly extended of late, and we are not now dependent upon West Indian supplies for imported fruits. Most of these in the Western Isles are grown under glass, and consequently are thoroughly ripened. The Bananas are sent in somewhat conical deep baskets of split bamboos, one bunch in each basket, and these too "go" at moderate prices; in fact, fruits are retailed in some of the shops at 6d. a dozen, which at one time, not so long since,

would have brought as many shillings. Oranges, of course, constitute an important Christmas supply. They are in many varieties, the Jaffa, the St. Michael's, the Mandarines and Tangerines predominating. The former come in large cases, the latter in small, neat, shallow boxes, each fruit wrapped in gold or silver paper, and having a very ornamental appearance. When half a dozen auctioneers, each attended by a hundred or more probable purchasers, the Floral Hall is a perfect Babel, shouts of sellers, buyers, and attendants, the rapid opening of barrels by herculean porters armed with axes, and the general commotion of arrival and removal constitute something that is quite indescribable.

Grapes, chiefly Gros Colman and Muscat of Alexandria, are included in the shops, average samples of the latter realising 7s. or 8s. per lb., the best being proportionally higher. Some consignments of Easter Beurré Pears from California look promising, but we have seen some unpacked in very bad condition. Pomeloes, Litchees, Custard Apples, and Mangoes are amongst the tropical fruits that occasionally find their way on to British tables, and all have been in the market during the past week. Nuts appear to be abundant, but they are scarcely equal to the demand, and prices rule high for good Walnuts and Cob Nuts. Barcelonas, Chestnuts, Almonds, and Brazils are abundant and good.

Concerning the vegetable supplies little need be said, as they are of the ordinary winter character, except perhaps that Brussels Sprouts are more in demand, and good samples have been the rule. It may have occurred to some who visit horticultural shows that considerable taste is frequently displayed in the arrangement of vegetables in competition, and very bright effects are produced in large classes. Vegetables have, however, recently been utilised for a very novel purpose—namely, the decoration of a dinner table, and the result was so satisfactory that it will probably soon find some imitators. During the recent visit of the Prince of Wales to Easton Lodge, Dunmow, Lady Brooke suggested an experiment of this kind, which was carried out by Mr. H. Lister to the entire satisfaction of all, including the Prince. Only small neat samples were employed, and as many bright colours introduced as possible, vegetables being exclusively employed. The idea is worthy of mention now when novelty is so eagerly sought in such matters.

What may be termed the miscellaneous special supplies consist mainly of Holly, which, by the way, is neither abundant nor good; evergreens of various kinds, and the indispensable Mistletoe. The last-named has given the auctioneers plenty of work lately, as the crates have arrived in piled-up vanloads, and have been disposed of in several thousands at each sale, the average from 7s. to 10s. each, the crates being 4 or 5 feet square, and closely packed with Mistletoe, the value depending upon the quantity of berries to some extent. Much of this comes from France, chiefly from Normandy and adjoining districts. "Christmas trees" (*Abies*) also arrive in immense numbers, and a sketch of one of the "forests" has been caught and shown at the lower part of the illustration. Most of these have been rather ruthlessly torn from the ground, are devoid of roots, and are not intended to survive the festivities of the season.

Altogether Covent Garden Market is a wonderful emporium, and an hour can be profitably spent at this season in inspecting its stores.

AMERICAN BLACKBERRIES.

HAVE you not made a jumble on the above subject? If "South Wales" remarks were meant strictly to apply to the American Brambles I fancy he is about the mark; but if he includes the Parsley-leaved Bramble then he is decidedly wrong in supposing no good crops are grown. There are many places where this variety is grown to perfection, where the fruit is gathered by the hundredweight, and it is certainly his own fault if he has failed to grow and fruit this variety well. But then it is, I believe, not an American but an English-raised variety, and so he may purposely have omitted it, though this is not likely, as it is always called American. Your hit at him on page 509 is very good, but of

course you know that no express trains run to John o' Groat's—not beyond Perth. I have often wished they did, as the travelling up there is abominably slow.—F. BOYES, *Beverley*.

[We are glad our correspondent has taken to writing again. His pleasant letter atones for our "jumble," and we shall not mind jumbling again if he will continue writing. We did not, however, jumble over the Blackberry if we did over the train. We studiously avoided the term "American" in our few lines of pleasantry on the page cited, and in order that there could be no mistake about the variety we meant both its scientific and popular name was given, and we fully expected "South Wales" would take advantage of the opportunity thus afforded him for a smart rejoinder. Judging from his reply on page 527 he either did not see the "point," or admits the Parsley-leaved variety as an American. If he places it in the condemned list we are bound to suggest that his verdict has been arrived at on insufficient evidence. The Perth terminus is quite sufficient for our purpose, for before reaching it by express train the traveller from the Land's End must of necessity pass Yorkshire, in which county the Parsley-leaved Bramble bears far heavier crops than we have ever seen Raspberries bear, and the individual fruits were as large as the largest Raspberries we suspect our correspondent has grown or seen, and he is not satisfied with small or inferior produce as his letter indicates. If he grew such crops of Blackberries as Mr. W. K. Woodcock, for instance, used to grow near Sheffield, his praise of them there is little doubt would be far greater than his condemnation of what he did not see, and could not be expected to see, if his long journey was by "express," and he has not denied the gentle assumption. Will Mr. Boyes oblige by stating his authority for his belief that *Rubus laciniatus* is an "English-raised variety?"]

ARMERIAS.

THE Thrifts or Sea Pinks, as they are frequently called, are pleasing ornaments of many parts of our British coasts, our Scottish mountains, and the Alpine regions of Europe. In summer our native species, *A. maritima*, adorns many acres in this neighbourhood, changing the dark colour of the merse land into a light pink, an effect produced by the myriads of flowers of the "Merse Daisies," as they are locally called, which spangle its surface so closely that at a distance the green of the grass is unseen. Two varieties of this species, *A. maritima alba* and *A. maritima rubra*, are frequently used as rock or edging plants, and are very useful for these purposes. These Armerias vary much in shade of colour, and I have frequently come across plants of the white variety in a wild state, but have never met with the deep red, although plants approaching it in shade may be met with. The object of these notes is not, however, to extol the beauties of our native plants, but to draw attention to two other species which far eclipse it in stateliness and in value for garden decoration. Our native Thrift is a humble plant, rearing its head only a few inches above its tuft of grass-like leaves as if conscious that our northern breezes have little respect for tender beauty, but our immigrants from a more southern clime rear their heads far above their leaves as if courting the warmer breath of the southern zephyr.

Armeria plantaginea is one of the best and most useful of the genus, forming fine tufts of broad grassy leaves, from which rise in summer tall stiff stems about 14 or 18 inches high with good sized flowers varying in colour from white to deep red. These flowers are useful for cutting, and are rendered of additional value by the fact that they may be dried and used as everlasting. *A. plantaginea* is a native of the Channel Islands, and is of easy cultivation in a light soil not too wet in winter. The other species, *A. cephalotes*, the large-headed Portuguese Thrift, has several synonyms. It has also been called *A. latifolia*, *A. mauritanica*, *A. pseudo-Armeria*, *Statice lusitanica*, *Statice pseudo-Armeria*, and also *A. formosa*. I have, however, an idea that there is another species under the latter name which is distinct from *A. cephalotes*. Its English name is also doubtful, as in addition to that given above it is also called the Great Thrift, and in the "*Hortus Cantabrigiensis*" it is named the Plantain-leaved Thrift, by no means an inappropriate name.

Although this species seems somewhat fastidious as to soil, and of a more delicate constitution than *A. plantaginea*, it is one which should by all means be secured and given a trial on rockwork or in the border where a warm situation comparatively dry in winter can be secured. *A. cephalotes* has much broader leaves, larger heads, and finer individual flowers than the other species. It is also taller in growth, reaching with me 20 to 24 inches in height. The colours are white to deep red. These Armerias may be increased by division when large enough, but the simplest mode of raising a stock is by means of seed, which is best sown in pots or boxes and the young plants pricked out when large enough. The

seedlings will vary in colour, and the produce of a packet of seed is generally small.

There are several other species, such as *A. alpina*, *A. Lauchiana*, *A. bracteata*, but the two described are the finest and most distinct and deserve to be better known.—S. ARNOTT.

PRUNING PEACH TREES.

THE season having now arrived when the pruning of Peach trees will be pushed on with all possible speed, whenever occasions present themselves, until the whole both indoors and out have been manipulated, a few remarks on this interesting and important operation will, I hope, prove useful. I do not pretend to write anything original on the subject, as old lessons must be repeated again and again for the benefit of each successive grade of the rising generation of gardeners. Fortunately it is no longer thought necessary to plant young Peach trees and wait two or three years before half the allotted space could be filled with fruit-bearing shoots. It frequently happens now that as much space is covered and as much fruit produced in two years as was formerly the case in double that time. When houses have to be refilled it is by far the most economical plan to purchase trees of good size to start with rather than to study economy in the first instance by planting small trees, which are a long time in filling the space at their disposal.

It often happens that well established young trees can be removed from outside walls. This is decidedly better than obtaining large trees from a distance, and smaller ones can be purchased to fill up the vacancies. Assuming that we are dealing with a newly planted house of young trees, the wood of which has during the first season extended to one-third or one-half the space they are intended to cover, if the wood is fairly even, well ripened, and the outline of the tree shapely and well-balanced, I would not in any case shorten the points of the shoots where there is plenty of room for extension, as by so doing we curtail the fruit-producing area of tree. The shoots should be simply thinned, so as to leave the bearing wood about 6 inches apart over the greater part of the tree, necessarily allowing them a little closer towards the base, so as to keep plenty of wood for filling up vacancies. Whenever branches are removed take especial care to reserve the young ones that spring from their base, so as to prevent unsightly gaps; and where there is not room for extending prune them back to one or two eyes, so as to form spurs from which others may be extended whenever they are required. In some cases it is desirable to leave shoots that have only a few inches of room for extension, for the sake of producing an even crop of fruit. As soon as the fruit is gathered remove such, as it will intuse new life into those springing from the base, enabling them to fill up the vacant space, and ripen their wood thoroughly.

In cases where the leaders have extended far behind the other portions of the tree they should be shortened back, so as to produce a well-balanced head. I am a firm believer in keeping the wood of Peach trees as evenly balanced as possible. Once let any portion of a tree which has a tendency to become strong at the expense of the other parts go unchecked, and it is often a difficult matter to restore the tree to its proper balance. A great aid towards securing this desirable end is to bend the strong shoots downward, giving them a rather sharp curve at the base, and keep them in such positions till the young growths are a couple of inches in length. By this means the flow of sap is diverted from the strong to the weaker ones to a certain extent. When very gross shoots are produced they should be entirely removed, except in positions where they are particularly wanted to produce a well-shaped tree. In such cases cut them to within an inch of their base, and when disbudding is performed select the weakest shoot. Whenever shoots are cut back take care to shorten them to either triple buds or a wood bud. In the former case it almost invariably happens that the central bud is a wood bud, and in every instance wood buds are easily distinguished from flower buds by their thin and elongated appearance.—H. DUNKIN.

WINTER FLOWERING HEATHS.

It not uncommonly occurs that plants of these bought in from nurseries are quickly damaged through insufficiency of water at the roots. If the plants are in a healthy condition when received they will be found to be more or less root-bound, and with numberless young rootlets in great activity. If the plants are allowed to be dried at root every one of these rootlets will perish, and the plants will suffer in consequence. On the other hand, the roots will continue increasing with great rapidity if the soil is kept in a

fairly moist condition, and the period that the flowers will continue in good condition be extended very much.

The worst places to keep these plants are hot dry rooms, but even there they may be had in fair health by free applications of water. These remarks apply more particularly to *Erica hyemalis*, *E. caffra*, *E. gracilis*, and *E. melanthera*, but young plants of *E. Cavendishiana* and the *E. ventricosa*, varieties which flower in spring, must on no account be allowed to be dried. The best position during winter is on a cool base, where the plants will require a minimum of water applied to keep the soil reasonably moist.

The plants may be grown on for a second year in the same pots if care is taken to place them in a position where they are shaded from direct sunshine during the greater part of the day; but such plants are of course not to be compared with those bought in. However, by transferring into larger pots fine plants may be produced. Free drainage, good peat and sand firmly rammed in, and attention to watering, are the chief items to bear in mind. After repotting the plants must be kept close for the first ten days, and until May they will be better where the protection of glass can be given them, but thereafter the growths will be sturdier and more healthy if made in the open air.—B.

LANCASHIRE PRIZE GOOSEBERRIES.

VERY few persons outside the exhibiting districts know anything about the large prize Gooseberries seen at the various Gooseberry shows in the midlands and the north, and the very great interest taken in their cultivation by working men chiefly. I have before me a copy of the "Gooseberry Growers' Register" for 1889, which records the exhibits and prizewinners at seventy-three Gooseberry shows held in Lancashire, Yorkshire, Staffordshire, and other northern counties during the year 1889: also tabulated columns showing the number of prizes won by each variety at all the Gooseberry shows for the year. For instance, forty-eight varieties of reds were exhibited, a variety named Bobby taking 127 prizes of various degrees, and the heaviest berry of the lot weighing twenty-nine dwts. London follows next with eighty-nine prizes, Lord Derby eighty-eight, Clayton seventy-seven, Dan's Mistake sixty-nine. Yellows: Leveller 155, Ringer 102, Lady Houghton eighty-one, Mount Pleasant, sixty-nine. Fifty-five varieties of yellow were shown at the various shows. In greens forty-five varieties were shown, and Surprise scored 105 prizes, Stockwell ninety, Shiner eighty, and British Oak seventy. In whites forty-five varieties were staged, and Careless scored eighty-eight, Transparent eighty, Hero of the Nile seventy-six, and Antagonist fifty-five. A record is also given of the heaviest berry of the year since 1809, each year recording the name of the sort and its weight, and the heaviest Gooseberry in all these years is London, exhibited in 1852, weighing over 37 dwts., but many others run it close in weight. For a long number of years the heaviest weighing Gooseberry of the year has ranged from 27 to 36 dwts.

Is the Gooseberry sufficiently valued as a dessert fruit? may be very safely asked. Many of these prize varieties are thin-skinned, luscious, and deliciously flavoured when well ripened, and because the Gooseberry is regarded as a common fruit, and so little attention is devoted to it, and so little knowledge exists amongst gardeners as to the merits of many of the prize varieties as a dessert fruit, that the poor Gooseberry is a neglected scion of our family of fruits beyond its uses for culinary purposes. An impression exists that they are poor croppers, but this is not the fact; but to obtain very large fruits for exhibition work thinning out is resorted to, and the plants get plenty of care. Well planted at first, with top-dressings and manure water in the fruit growing stage, but woe betide the exhibitor who does too much when the fruit is ripening.

Of the varieties generally grown in our gardens old Crown Bob holds a place, and has done so for nearly a century. The Warrington or Ashton is everybody's Gooseberry, so also is Whitesmith. Golden Drop or Early Sulphur, Green Gage, Rambullion, Whinham's Industry are all first-rate, but none of these grow to the size of the Lancashire prize varieties. For delicious flavour give me still the old Red Champagne, small; but what a *bonne bouche* when quite ripe.

The caterpillar of the Gooseberry and Currant moth is a troublesome customer, but a little care at the proper time will do much to prevent its ravages. Either a top-dressing of gas lime or the removal of the top soil and burning it is one step, and the dressing of the trees before Christmas is another, using a mixture of soft soap and paraffin oil. Then a steady look out very early in the growing season for the caterpillar. These are all steps towards

the preservation of the Gooseberry tree from the ravages of the caterpillar.—RIBES.

SELECT HARDY CYPRIPEDIUMS.

AMONG hardy plants we have none possessing so many charms as the best hardy Cypripediums. Several species are even more beautiful than are many from tropical climes, and while the latter can only be grown in heated structures, and are therefore expensive to cultivate, the former may be grown by a far more numerous body of amateur horticulturists, provided they give due attention to a few simple though essential details. Anyone making a start with hardy Cypripediums should bear in mind that they cannot well be accommodated in the border usually devoted to hardy herbaceous plants; therefore it is prudent not to put them there, as the idea of obtaining satisfaction from them in this position will be vain. The position best suited for their requirements is almost sure to exist in any garden, and if not it is easily made. One of the primary considerations should be a partially shaded, low-lying, and naturally moist place. The question of suitable soil will next require attention, for the right material will scarcely be forthcoming in many gardens, and the natural soil will therefore have to be removed to a depth of 2 feet. Prior to proceeding with this part of the work a rough idea of the outline of the bed should be decided upon. This being done excavating the soil is simple enough. The soil being removed to the above depth, next cover the bottom with about 6 inches of brickbats, broken pots, or any similarly rough material that will form an efficient drainage, for although decidedly moisture-loving, stagnant water or anything approaching it must be carefully avoided, and by covering the potsherds with moss litter or rough sods of common peat an effective drainage will be insured.

The filling-in of suitable soil forms the next item. This should consist of rough fibrous or spongy peat and well decayed leaf soil in equal proportions, filling the hole to within 6 inches of the surface, which, with the sides of the bed sloping to this level, would have a foot thick of soil for the Cypripediums. Such a position as this might remain a veritable home for these charming plants for many years with an annual mulching of well decayed manure.

In planting them it is only necessary to cover with about an inch of soil, spreading the roots out carefully, and not burying them in a mass to quickly decay and permanently injure the plants. This is important, particularly to those who have but little experience with them. To commence with, I strongly recommend the following as not only perfectly hardy, but robust and vigorous also.

C. spectabile must, of course, be allotted the first place, since no other can equal this glorious plant when seen in established clumps in its full beauty. I have never forgotten the earliest plant I knew. Huge masses they were, producing six or eight stems, and each stem a pair of its lovely flowers. They were planted in a shady peat bed, which was favoured by a supply of water (at option) from a fountain in a higher part of the garden. During summer the bed was always in a state of semi-saturation, which suited them splendidly. The plant grows about 2 feet high when established, producing leafy stems, and terminating with its charming flowers. These vary considerably, the lip sometimes being of a bright rosy carmine, in others rose, while in many others the tinge of rose is delicate in the extreme, while the sepals and petals are white; but whatever shade one may chance to have, all will be found chaste and beautiful beyond compare. This handsome species is a native of North America, whence our leading hardy plant dealers invariably procure their supplies annually in December. I mention this fact for this reason, that if the plants are procured at once and planted as directed, the majority of the roots may be preserved, a highly desirable matter where success is coveted. It may interest not a few who have no convenience for making an artificial bog for these and similar plants, that this charming species may be grown in pans of peaty soil kept moist, either in a shady corner of a cold frame or in the greenhouse; in fact, many importations of less than twenty years ago, when its complete hardiness was not

fully realised, were either flowered in the greenhouse or protected in frames, and although they lend themselves admirably to this mode of treatment, and therefore placed within the reach of a greater number, it should be borne in mind that it is perfectly safe without any protection whatever.

C. Calceolus, a British species, now probably extinct, preferring loamy soil, for which provision can easily be made. In height it is usually a foot or 18 inches, and producing one or two flowers. In this the sepals and petals are brown, and the lip yellow. It is of easy culture when good tufts are obtainable, but too frequently many of the roots are torn off by the collectors in their native

and brownish yellow. Another yellow flowered species, with slightly fragrant flowers, is *C. parviflorum*. The individual flowers are smaller than usual, but by reason of its free growth and flowering should be included among the best kinds for this purpose. Some other exquisite species are still remaining, but as these require special treatment we will not risk them in the general collection, and will refer to these on a future day.—J. H. E.

A WALL OF TOMATOES.

IN the Journal of November 21st, page 436, I notice "J. H. W." writing on outdoor Tomatoes, and his remarks are good, especially as to

FIG. 70.—A WALL OF TOMATOES AT EWENNY PRIORY.

homes. Fortunately it is to be had cheaply, so that several may be grouped together to form a cluster.

C. acaule, a most distinct and handsome species, about 8 or 9 inches high, the flowers issuing from a pair of ovate, hairy leaves. Generally of a lovely rose colour, or delicate rose shaded with white. The flowers are also much longer than is usual, and the general aspect of the plant is different, particularly the pouch-like appearance of the lip. This species should be planted in a more sandy soil, and in the dryer portions of the bog.

C. pubescens is fortunately not only a very ornamental species, but one which is established quite readily. It resembles *C. Calceolus* in general appearance, but does not appear content with the soil which suits that species; while in the ordinary peaty bog it grows and increases freely. The flowers, however, have not the clear yellow so conspicuous in the lip of the British plant, but are larger

the time for sowing and planting, as I find our summers are too short to grow them outdoors unless getting good plants to start with. "J. H. W." did not mention the variety that has proved best with me and many others in this district, and I have therefore taken the liberty of mentioning it. It is Webb's Sensation. It is such a handsome fruit I did not venture to grow it outdoors extensively until this year, and to my surprise it is the best I have ever grown for size, quality, and productiveness. We grew several dozens of plants in different parts of the gardens where I could find a little vacant piece of wall. We also grew a great many in pots in the vineries against back walls, also in an orchard house trained to a cord or stakes; by doing so we have a continuous supply for many months. We placed fifteen plants out in front of our Melon and Cucumber house, the wall being 50 feet long and 2 feet 6 inches high, we did not allow the plants to grow any higher. Mr. Muir of Margam Park called to see me on September 6th, and was so surprised, he advised me to have them photographed, count the fruits, and weigh a dozen of them. We had gathered some from this wall before Mr. Muir's arrival, and there

remained 670. One dozen weighed 8 lbs. 10 ozs.—GEO. HAWKINS, *Euceny Priory Gardens.*

[The illustration has been prepared from a photograph of the wall in question furnished to Messrs. Webb & Sons.]

TREATMENT OF SOILS, MANURES, AND CROPS.

PEAS.

I HAVE had the pleasure of seeing Peas sown outside in December, and all the crop gathered and ground cleared in May. I would recommend this to all where the ground will allow the sowing in December, and there is no possibility of the seeds being killed. Sow Sangster's No. 1 and Chelsea Gem; I prefer the former where sticks and ground are plentiful, otherwise I would depend upon Chelsea Gem for this sowing. It has a good pod, fills well with good peas, is excellent in flavour, and it requires no sticks.

The ground should be well manured and dug. It is proper that Peas follow any variety of the Brassica family, and suppose that we take a plot left vacant by autumn Cabbages, or an early supply of Autumn Giant Cauliflower, drills should be drawn 3 inches deep to 6 inches wide, and for Sangster's 4 feet, and Chelsea Gem 2 feet 6 inches apart. Sow evenly, but not too thick, and cover lightly. These will begin to push through during February, and must have some soil drawn up to them to protect them from the frost. Use plenty of brushwood for the bottoms; I prefer Beech sticks, and clip the tops off level, so as to give a good appearance.

Should the soil not allow of sowing in December or January for the first crop, procure some good fibre turves about 1 foot long, 4 inches wide, and 3 inches deep. Lay them grass downwards and cut out a groove 2 inches wide and 1½ deep; sow the Peas in these, and stand them in a light greenhouse or frame. When the Peas are up and the turf full of roots, another turf the same size can be used or placed under them. Stand them out, or draw off the lights, to harden them, and when weather permits, and they are ready, dig a trench, plant them out, and protect from cold winds and frost for a time. I have done this in cold wet districts, and have been very successful. I like turves better than boxes, as the soil is often loose it breaks and spoils the roots. A sprinkling of soot and lime or dust coal should be put along those planted outside, and well mulch after sticking.

I think an excellent plan that may be adopted is to begin in January, and sow every month one, two, or three rows, to come in as a succession. The sowings can be carried on up till August. I do not care much for late Peas, but they must be had, and the best method to adopt is to dig a trench similar to that for Celery, and dig in a good supply of manure at the bottom, and during their growing period give copious supplies of liquid manure. The Peas I have found best for the early, second early, and late sowings. Early sowings, Sangster's No. 1, William I., and Veitch's Selected Extra Early. These are for the sowings before Christmas or January; or Chelsea Gem instead of all the above. A second sowing of the above can be made if the demand is great. For second or general crop I prefer Prodigy; it is a fine, green, wrinkled Marrowfat, an enormous cropper, and it seems to be more self-supporting than most Peas. It gave great satisfaction in the dining-room. I also like Telephone, Stratagem, and Gladiator, and they give great satisfaction as to flavour. For late sowings Sturdy must take the palm for flavour, bearing, and for lasting longer than any other Pea; but Autocrat, Maclean's Best of All, and British Queen can be relied upon to give general satisfaction. I have given the constituents of the Pea, which must act as a guide to the cultivator as to the nature of the manure required. They are identical to the Vetches and Tares, and therefore if the plot can be treated as advised for other crops it will be found a success—that is, dig and sow with Vetches or Tares, and turn them in or trench in the spring.

BROAD BEANS.

The Broad Bean is so hardy that it can be cultivated almost with indifference. Some say they will not do on cold wet land if sown early. I have seen them good from very early sowings in almost rocky soil to nearly pure sand. Like the Peas it should succeed Potatoes, Carrots, Parsnip, Brassicas, and the Turnip; but what is more important is it can be grown under difficulties. It is not a favourite, and I will give it little room here. Sow Mazagan in November. In February sow the main crop of Veitch's Improved Longpod, which is an exhibition variety; and successions of Early Longpod and Broad Improved Windsor in March and April if wanted.

KIDNEY BEANS.

I think the Kidney Bean is a favourite with all. I would sow on a good warm border at the end of April Canadian Wonder for the early supply, and a few rows can be had here and there where

small spaces are vacant. The sowings should take place about every fortnight till the end of June. The best sorts are Canadian Wonder, Ne Plus Ultra, Longpod, Negro, and Newington Wonder. Sow in rows 1½ to 2½ feet apart, and draw the soil up to the plants, thereby leaving a trench, which if filled with liquid manure the finer will the crop be.

SCARLET RUNNER BEANS.

Everyone who possesses a yard of garden is able to procure a supply of these Beans in most seasons, but a very hot summer offers an exception to this rule. The scarcity of Runner Beans can best be shown by stating that the price of a bushel was 10s. in 1887, a hot summer, while in 1889 they fetched just one-tenth of that sum. How was it that they were scarce? and how could the scarcity have been averted? I can speak for the success of ours, which was due to having a good trench prepared for them, and with fully 6 inches of manure dug in at the bottom, and to their receiving several waterings of liquid manure during their growing season. In 1889 I must say that ours were the finest I ever saw, and the secret of this was that they were grown upon the plot of land heavily dressed and trenched the year before for Brussels Sprouts. I claim no credit for this, as it was by accident they were placed there without any preparation.

They love to run in a cold manure during summer, and a trench best suits them. I would sow Veitch's Mammoth Scarlet the first week in May; sow the seed as close again as wanted, and thin out to proper distance when starting to run. Sow Painted Lady and Scarlet at the end of May for a succession. Keep the hoe going amongst them, and well water during hot dry weather.

While on a visit to Mr. Smythe of Basing Park Gardens, he showed me a fine sowing of a dwarf Runner Bean, in which he was taking a special interest, and judging by their power to stand almost as erect and self-supporting as the French Bean, and while bearing a heavy crop of pods too, every one being preserved for seed. If the progeny prove as good as the parents appeared to me, this will prove a great acquisition to those that dislike tall runners and others that require all the space that can be spared without being shaded, and also to plant Winter Greens between them.—G. A. BISHOP.

OUTDOOR PEACH CULTURE.

I WAS much pleased to read an article on the above subject on page 482 of your valuable paper, and, like Mr. Thos. Record, I hope some day to see more attention given to this system of growing Peaches. Our forefathers were able to produce excellent crops of fruit on trees outside, and surely our climate has not undergone such a change for the worse as to prevent gardeners of the present day obtaining like results. I have always maintained that if anything approaching the same attention and care were accorded to outside trees as to those under glass good crops would be the rule, and not an exception, as they are at present. I admit there are some gardens so badly situated as to render the cultivation of Peaches outside impossible, but in the majority there is nothing to prevent their being grown satisfactorily. If the trees are on a south wall I do not consider it necessary to devote more than 4 feet of the border to the trees, as by judicious lifting and root-pruning the trees are kept in a more healthy and fruitful state, and the roots are kept nearer the surface and in smaller compass, and are therefore more easily fed, and the remainder of the border can be utilised for early vegetable crops.

I have only had to record one failure—viz., this season—during the last ten years. The nine years previous we had splendid crops of excellent fruit, and I agree with Mr. Record that for colour, firmness of flesh, and briskness of flavour they could not be surpassed by the best examples of indoor fruit, and that on a border which has been cropped annually to within 4 feet of the wall with such crops as early Peas, Potatoes, and salads, besides raising all the Brassicas for planting, and at present the trees look promising for next season. We only protect them when in bloom, and then only with a strip of canvas 54 inches wide stretched from the top of the wall at an angle of 60°, and the damage from frost has been almost nil.

In regard to pruning I consider it best to cut out all wood not required immediately the tree is cleared of fruit, so as to give that required for next season the benefit of all the light and air. The disbudding, syringing, and feeding with liquid manure should be as carefully attended to as it is in the case of their more favoured brethren under glass.

Gardeners who are favoured with three or four good Peach houses can maintain a succession of fruit independent of outside walls, but the majority are not so happily situated, only having one or two small houses devoted to Peach culture. To such I would say, Do not believe those who say that Peach culture out-

doors is a failure until you have given the system a fair trial ; and when you have done that I have no hesitation in predicting you will agree with Mr. Record and myself that it is possible to produce as good crops of Peaches on outdoor walls at the present time as were ever produced before Peach houses became so plentiful.—LANCASTRIAN.

TO OUR READERS.—At this, the season of good wishes, we desire that all our readers will believe in the sincerity of our hopes that they will largely share in all that is embodied in the time-honoured sentiment—A MERRY CHRISTMAS.

— MR. RICHARD PARKER.—I beg, with your permission, to offer my hearty congratulations to Mr. Richard Parker, both on his success as an exhibitor, and also on his being strong enough and fair enough to admit the assistance of his foreman, Mr. Crooks. This is, to a persevering and industrious man, a great encouragement, and deserving men appreciate such recognition of their services.—R. KIRBY, *Oulton Hall, Leeds*.

— THE BIRMINGHAM GARDENERS' ASSOCIATION.—At the meeting on the 10th inst. Mr. John Pope, nurseryman, read a paper on "The Big Gooseberry," pointing out that many of the large Lancashire prize varieties were generally very little known outside of the prize Gooseberry growing districts ; and urging that many of these large varieties should be more cultivated and used as dessert fruits, as several of the prize varieties attained a large size and possess excellent flavour. Varieties of excellence in this respect were named, and the cultivation and enemies of the Gooseberry has in the shape of insects were referred to.

— CHRYSANTHEMUM SHOWS.—The Bradford Society will hold their annual Show on Friday and Saturday, November 7th and 8th ; the Croydon Society's Show is announced for November 12th, 1890.

— THE RAISIN CROP OF CALIFORNIA this year is reported to be a failure. Rain came during the dry season, and being wholly unprepared for it, the result is much greater damage than would otherwise be probable. Drying Grapes for raisins has in many places superseded the making of wine, which has been overdone in California.

— IT is said the LATE MR. JOHN BALL, F.R.S., has bequeathed his botanical library and herbarium to Sir Joseph Hooker, to the Director of the Royal Botanic Gardens at Kew for the time being, and to the President of the Royal Society for the time being, requesting them to give the same to such person or persons or public institution in this country, the British colonies or elsewhere in the world, as they or any two of them may select, with the sole object of promoting the knowledge of natural science. Right is, however, reserved for Kew to select previously such specimens or books as it may want.

— QUILLAIA SAPONARIA.—At a recent meeting of the Linnean Society Mr. Thomas Christy exhibited some bark of *Quillaia saponaria* from Chili, which has the property of producing a great lather, and is extensively used for washing silk and wool. It is now found to solidify hydrocarbon oils and benzoline, and thereby to ensure their safe transport on long voyages, a small infusion of citric acid rendering them again liquid. The plant named is a hardy evergreen shrub, a member of the Rose family. It is a native of Chili, and was introduced to this country in 1832.

— THE Economic Museum, Calcutta, has completed and despatched the first instalment of important Indian fibres required by the Indian Office for presentation to the Museums of the Royal Botanical Gardens at Kew and Edinburgh, and to the Chambers of Commerce at Dundee and Manchester.—(*Nature*.)

— AMERICAN APPLES.—The exports of Apples from all American ports for the week ending November 23rd, as reported by A. C. Lombard & Sons, were 48,211 barrels, including 8933 barrels from Boston, 12,277 barrels from New York, 27,001 barrels from Montreal. For the

season the total exports have been 371,608 barrels, including 81,081 barrels from Boston, 90,244 barrels from New York, 162,526 barrels from Montreal, 23,733 barrels from Halifax, 12,000 barrels from Annapolis. For the same time last year the total exports were 784,500 barrels, including 196,011 barrels from Boston, 242,319 barrels from New York, 291,692 barrels from Montreal, 54,484 barrels from Halifax. Boston's week's shipments were 8482 barrels to Liverpool, and 451 barrels to London.

— WE are informed that PROF. BORNMULLER, Director of the Botanic Garden at Belgrade, has started on a twelve-months botanical tour through Asia Minor. Beginning at Amasia, he will travel through the country between the courses of the Kisil-irmak and Euphrates southward to the completely unexplored mountains of Ak-dagh. The *Botanical Gazette* says that this country has only once been explored, thirty-five years ago, by the Russian botanist Wiedemann. According to the same authority, Prof. Bornmüller is a young and very successful explorer, with a great deal of experience, especially from his long journey in 1886, through Dalmatia, Monte Negro, Greece, Turkey, East Bulgaria, and Asia Minor. His original collection will be transferred to Weimar, where it will be carefully gone through by Prof. Hausknecht.

— BIRDS A FRIEND TO THE GARDENER.—One of the few sources of enjoyment in the garden, Christmas week, is a walk in front of my outdoor protected wall Chrysanthemums, to observe the late blooms expanding. You may be surprised to hear the open-air temperature here to-day is 50° Fahr., and the frost has not injured a petal under the canvas framework. To-day I was greatly amused watching four small birds, something larger than wrens, colour greyish green with white wing splashes, black head, darting nimbly from bloom to bloom turning over the petals, and evidently feeding on aphides. Would some ornithophile say what this useful lively little bird is? I have never noticed them in towns before, and they evidently find my Chrysanthemum screen a comfortable night retreat. Would it be the lesser spotted woodpecker (*Picus minor*)? It is, I believe, an insect feeder.—W. J. MURPHY, *Clonmel*.

— AN extremely bright Californian plant is figured in the "Botanical Magazine" for the present month (t. 7092). This is CLINTONIA ANDREWSIANA, which has its flowers in a dense terminal umbel, and the colour is described as "dark claret purple," though it is depicted of a bright rosy red. Mr. J. G. Baker says :—"Clintonia is a genus of baccate Liliaceæ, which contains six species four of which are North American and two East Asiatic. This is the only species in which the flowers are at all showy. In all the others they are greenish-white. Two of them were figured long ago in the 'Botanical Magazine' (tabs. 1155 and 1403), both under the name of *Smilacina borealis*. *C. Andrewsiana* is very local, being confined to the coast ranges of California, from Humboldt County to Santa Cruz. No specimen existed at Kew, either in the herbarium or the garden, till very lately. Our drawing was made from two plants that flowered last June, one in the herbaceous ground at Kew, and the other in the Botanic Garden at Edinburgh, from which it was kindly sent to the Royal Gardens by Professor Bayley Balfour. It requires to be grown in a shady position in a bog or peat bed."

— CARNATION MRS. REYNOLDS HOLE.—I can speak with confidence in favour of this Carnation for outdoor flowering. We have a good number of border varieties which succeed well in a cold heavy soil, and the one in question was the most admired of all last season. The colour is very pleasing, and quite distinct amongst Carnations and other flowers. For flowering out of doors the blooms do not split the calyx, a great point in its favour. It is a good grower, producing "grass" abundantly. New plantations are made annually early in October, and if a mulching of sifted vegetable refuse and wood ashes is applied between the rows the plants stand the winter well, but we always contrive to have them well rooted at planting time by layering early and using plenty of sandy soil, old potting refuse, to which is added some leaf soil. Into this the roots run more freely than they would into the ordinary garden soil, thus we are enabled to lift the rooted layers with a good ball of earth attached. The planting of a new bed in this manner gives scarcely any check to the plants, certainly much less than where late layering is practised, and ordinary soil used, especially if it be of a heavy character.—E. M.

— THE following botanical appointments are announced :—The Directorship of the Botanic Garden at Berlin, vacant by the death

of Dr. Eichler, having been conferred on Prof. Engler, of Breslau, Prof. Urban becomes Second Director of the Berlin Botanic Garden; and Prof. Prantl, of Aachen, succeeds Prof. Engler as Director of the Botanic Garden at Breslau. Prof. Sadebeck, of Hamburg, is appointed Director of the Botanic Garden in that town, in the place of the late Dr. Reichenbach. Dr. G. von Lagerheim vacates the Professorship at Lisbon, to which he was lately appointed, and goes to Ecuador as Professor of Botany and Director of the Botanic Garden at Quito. Dr. H. Molisch, of Vienna, takes the chair of the late Dr. Leitgeb in the Polytechnic at Gratz. Dr. F. Hueppe is appointed Professor of Bacteriology at the University of Prague, and is succeeded in the same chair at Wiesbaden by Dr. G. Frank, of Berlin. The venerable Professor von Naegeli retires from the Directorship of the Botanic Garden at Munich. Mr. F. S. Earle, Prof. E. S. Goff, and Prof. L. R. Taft have been appointed special agents in the Section of Vegetable Pathology in the United States Department of Agriculture. Mr. H. H. Rusby has been appointed Professor of Botany and Materia Medica in the New York College of Pharmacy.

— **OXALIS FLORIBUNDA AS A BASKET PLANT.**—The peculiar nature and graceful habit render the *Oxalis* especially adapted for this purpose. The brown insignificant little tubers tell no tale of the beauty hidden within, nor how, planted in small companies of four or five, they are ready in August or September to begin life over again, and from the slender drooping stems, with their leaves of Clover shape, to the clusters of blossoms, dainty and sweet, to charm everybody the whole winter long, and half the spring beside. They vary a little in habit, the yellow and rose varieties drooping more in flower and leaf than the white, which holds itself rather erect, yet is just as beautiful and as well adapted for hanging purposes, while their habit of bloom in all winter-blooming varieties is equally profuse. Pot as early as possible in good sandy loam, and three, four, or five in the same pot. After flowering the foliage will turn yellow, and should be allowed to dry gradually, when the bulbs can be shaken out and repotted at the proper time. While many plants in the window are often chary of bloom, to the great disappointment of their owners, the *Oxalis* has this merit, that it is never without flowers in season, and will reward by its abundance of bloom the attention bestowed upon it. It will entirely fill any basket, to the exclusion of all else, for it is a vigorous grower, and its leaf stems are equally profuse with its flowers.—H. K.

— **THE American Agricultural Department** has been making careful inquiry as to the **FOOD OF CROWS**; and the result, as set forth in a report by Mr. Walter B. Barrows, is likely to surprise those who have always contended that these birds do very much more good than harm. It is not disputed that they destroy injurious insects, that they are enemies of mice and other rodents, and that they are occasionally valuable as scavengers; but these services are slight in comparison with the mischief for which they are responsible. The injury done by them to Indian Corn, Wheat, Rye, Oats, and other cereals is enormous. According to one observer, the crow eats corn "from ten minutes after planting until the blades are 3 inches high;" and more than a score of other observers testify that he not only pulls up the young plants, but digs up the newly sown seed. His depredations extend to Potatoes, Sweet Potatoes, Beans, Pea Nuts, Cherries, Strawberries, Raspberries, and Blackberries; and he widely distributes certain poisonous plants, the seeds of which are improved rather than impaired by passage through his digestive organs. As if all this were not enough, it is shown that the crow eats beneficial insects, and that he makes himself a most formidable nuisance by destroying the eggs and young both of domesticated fowls and wild birds.

— **RETARDED GERMINATION.**—"E. A." writes as follows in *Nature*:—"I shall be much obliged to any of your readers who can give an explanation of the probable cause of the above phenomenon, which I have remarked this year. I sowed a number of patches of seeds of various hardy annuals in the garden in the last week of April; about half of them came up after the usual interval strongly and regularly. Such were *Calendula Pongei*, *Convolvulus minor*, *Lavatera trimestris*, *Collinsia bicolor*, *Iberis* (white and red), *Specularia speculum*, *Linum rubrum*, &c. Then there were some of which a few scattered seedlings made their appearance at this time, and after an interval of about six weeks the greater part of them also came up; among these were *Eutoca viscida*, *Nigella damascena*, *Sphenogyne*, and *Clarkia pulchella*. Thirdly, there were some of which I quite despaired. *Mignonette*, however, appeared thinly about the end of June, and at intervals till August;

and in the middle of June a few plants (in proportion to the seed sown a few) of *Linaria bipartata*, *Madia elegans*, and *Xeranthemum* came up, one consequence being that the last-named did not flower. Some of the seeds were obtained this spring from seedsmen, some were my own collection of the last year or two; of the latter were *Calendula*, *Lavatera*, *Convolvulus*, *Specularia*, *Eutoca*, *Nigella*, *Sphenogyne*, and *Mignonette*, so that cannot be said to give any clue. The conditions for germination and growth were favourable, and the season also. I have never remarked before any annuals so long in appearing above ground, though in some herbaceous plants I have noticed it—*e.g.*, *Gaillardia*, *Myosotis alpestris*, and *Anemone coronaria*."

— **SCHOOL ALLOTMENTS.**—At the little town of Sherborne, in Dorsetshire—which, by the way, possesses a public school, not nearly so well known as it should be—there has been for many years past a system of small allotments amongst the parochial school children. It was inaugurated so far back as the year 1857, when the Abbey National Schools were founded. Each allotment is stated to be about $3\frac{1}{2}$ perches, or lugs as they are called in the west country vernacular, this being the forty-sixth part of an acre, to a plot, for which a rent of 2s. is paid. Mr. Gordon, the Government school inspector, in reporting on the subject, says that the little garden patch has fitted boys to gain their own living to some extent, and he attributes to it the exceptional success of the allotment system generally in the neighbourhood of Sherborne. The gardens also furnish a healthy exercise for the boys, as well as a relief from school duties. More than that, they have been found to promote increased attendance at school, for, apart from the boys, the parents who derive a benefit from the produce take an interest in the system. Most people will agree with Mr. Gordon in wishing to see the example of the little Dorsetshire town followed more generally elsewhere, so far as the system is concerned, although there seems to be no good reason why so high a rent should be charged. Half the amount would be much more reasonable, and more likely to conduce to the successful introduction of the plan in other places. In fact, in the only other instance we have heard of, the allotments are given to the boys rent free. This is at the British Schools at Elby, in Gloucestershire, where ever since 1840 there have been about twenty school allotments of $2\frac{1}{2}$ perches each, distributed amongst the boys in the order of seniority or merit, which, a correspondent writes, are always eagerly sought after and highly appreciated, as well as exceedingly well cultivated, by those who are fortunate enough to obtain them.—(*Agricultural Economist*.)

— **THE usual monthly meeting of the ROYAL METEOROLOGICAL SOCIETY** was held on Wednesday evening, the 18th inst., at the Institution of Civil Engineers; Dr. W. Marcet, F.R.S., President, in the chair. Thirty-nine new Fellows were elected. The following papers were read:—1, "Report of the Wind Force Committee on the Factor of the Kew Pattern Robinson Anemometer." This has been drawn up by Mr. W. H. Dines, who has made a large number of experiments with various anemometers on the whirling machine at Hersham. Twelve of these were made with the friction of the Kew anemometer artificially increased, seven with a variable velocity, and fourteen with the plane of the cups inclined at an angle to the direction of motion. In discussing the results the following points are taken into consideration—viz., the possibility of the existence of induced eddies, the effect of the increased friction due to the centrifugal force and gyroscopic action, and the action of the natural wind. The conclusion that the instrument is greatly affected by the variability of the wind to which it is exposed seems to be irresistible; and, if so, the exact value of the factor must depend upon the nature of the wind as well as upon the mean velocity. There is evidence to show that during a gale the variations of velocity are sometimes of great extent and frequency, and there can be but little doubt that in such a case the factor is less than 2.15. The one point which does seem clear is that for anemometers of the Kew pattern, the value 3 is far too high, and consequently that the registered wind velocities are considerably in excess of the true amount. 2, "On Testing Anemometers," by Mr. W. H. Dines, B.A. The author describes the various methods employed in the testing of anemometers, points out the difficulties that have to be encountered, and explains how they can be overcome. 3, "On the Rainfall of the Riviera," by Mr. G. J. Symons, F.R.S. The author has collected all the available information respecting rainfall in this district, which is very scanty. He believes that the total annual fall along the Riviera, from Cannes to San Remo, is about 31 inches, and that any difference between the several towns has yet to be proved. 4, "Report on the Phenological Observations for 1889," by Mr. E. Mawley. This is a discussion of observations

on the flowering of plants, the appearance of insects, the song and nesting of birds, &c. Taken as a whole 1889 was an unusually gay and bountiful year.

ROOT-PRUNING.

In the first place even old trees of some kinds will bear root-pruning, but not all alike. We have within these last twenty years root-pruned Pear trees in so severe a manner as would have been totally destructive of the constitution of the Peach. The trees were growing against a wall having a north-eastern aspect, and were, to all appearance at least, thirty or forty years old. Indeed, their trunks at the base were at the time of the operation nearly a foot in diameter. These trees had been useful bearing trees some years previously, but had ceased to be productive, producing breastwood nearly a yard from the wall. A former gardener, lamenting their barrenness, had trenched a huge quantity of manure in at their roots, which was the only cure known to him for all vegetable diseases. The best of the joke, however, remains; the trees had huge old spurs all over them, extending 6 inches from the wall, most of them of a peculiarly remarkable character; these he at the same time shaved clean away. What, of course, might have been anticipated did indeed occur; the trees made what was termed capital new wood, and this, according to the most approved ancient recipe, was scientifically spurred back with the idea of generating fruit spurs. The obstinate trees, however, had been so much accustomed to run riot that they became actually more unmanageable, and instead of yielding their contributions to the proprietor's fruit room they continued year by year to augment the faggot pile. Still the worthy who managed them persisted in spurring back with an amount of patience which really deserved a better fate. In this state, then, we found the trees twenty-two years ago when next March arrives. We had then been what may be termed dabbling in root-pruning somewhat secretly, for in those times we could not afford to be laughed at. Ringing also had been practised, and in a year or so afterwards these huge Pears had a ring of bark removed of some 4 or 5 inches in diameter all round the bole. "Kill or cure" was the maxim. We will not go so far as to say that the trees made as much breastwood as ever, but truly they still rambl'd away disregarding our puny efforts. Neither, as far as we remember, were any amount of blossom buds produced worthy of notice; and, strange to say (old as the trees were, and possessing a huge excrescence of old bark nearly an inch in thickness), the wound made by ringing commenced healing with such rapidity that in a couple of years we could barely discern the place whence the bark had been removed.

Finding that ringing would not reach the evil recourse was next had to root-pruning, and as the trees showed such an amount of hardihood we determined that this business should not be half done. An excavation was accordingly made in front of each tree opposite the bole, and at about half a yard distance from it; and here we cut through every root which presented a barrier to such proceedings, feeling assured that some enormous tap roots had penetrated the subsoil, which is what is termed by the country people a "booty sand," that is to say, an adhesive material, which appears to blend the marly with the sandstone principle. After passing through or between huge black roots we indeed met with the tap roots, and really one tree stood more like a three-legged stool than anything else. Three huge black roots had struck down almost perpendicularly. Here, then, lay the true secret of the enormous amount of breastwood. These fangs were cut away, and a great sacrifice this appeared. We here found, too, the stratum of manure before alluded to at about 4 feet in depth, or nearly so; it had become in time a complete humus, or peaty-looking substance, and was crossed in all directions with roots. The soil was then filled in, and, it being the month of December, we waited with some anxiety to see how far this strong operation would affect the production of breastwood the following spring. April and May arrived, but what a change had occurred! The trees could scarcely develop a shoot of 6 inches in length all that summer, and we now found that cutting away the roots, or in other words restricting the supply of food, was a more powerful operation by far than merely arresting or clogging the vital action for a time by means of ringing. The trees now became short-jointed; spurs, real natural spurs, began to form, and thenceforward we began to eat Pears again. The trees have continued to bear tolerably good crops in most seasons since, but, strange to say, they are again inclined to become somewhat over-luxuriant.

I ought to mention here that the cutting of the roots was so severe that the main trunk of the trees (which I before named as nearly a foot in diameter at bottom, and might be about 6 inches at the top) sunk, and became detached from the wall which it before joined, and at this time the main bole hangs 6 or 8 inches from the wall at the top.

First in order, then, we would name the Pear as the most eligible for this operation; this, we think, has become tolerably manifest. Next to the Pear we think the Apple may be placed, then the Plum, next the Peach and Nectarine, then the Cherry and Apricot. We speak now of the ordinary wall fruits, and the order in which they are here placed is intended to point both to their vital powers of endurance, as also to the frequency of the cases which may be expected to present themselves to fruit growers.

To begin with the Pear, we must point to the fact that on the free stock this tree is peculiarly liable to tap roots. On the Quince it is quite another matter; here the roots are of the most fibrous character, so much so that we can barely conceive a case in which root-pruning becomes necessary. We, nevertheless, have some against us who, it would seem, root-prune even on this stock periodically. We must, however, remember the object, which is to produce trees so dwarf and compact in character that the holder of a score square yards may possess his miniature fruit garden and vegetables to boot. As to the free stock, then, if Pears are growing luxuriantly on these without bearing, it is almost impossible to root-prune too severely, at least the deeper roots. If in an orchard, and trees are of some size, they may be curtailed all round also; the amount of root removed bearing, of course, a direct ratio to the amount of luxuriance. In the espalier border we must be content to get at them how we can, remembering what we before observed that even the cutting of one side will assuredly affect the whole system of the tree, although perhaps not in an equal degree.

The Apple is found in such a variety of shapes and sizes that it is not very easy to generalise a system of root-pruning, at least so as to make ourselves generally understood by those who have not yet dabbled in its practice. We may first observe that the Apple even on the Crab or free stock is not quite so liable to tap roots as the Pear on the wild or free stock. Another point we may name also—the Apple with an over-severe amount of root-pruning is apt to become infested with red spider during the first summer after the operation. This we have repeatedly proved, and the remedy is sometimes worse than the disease. We introduce this caution to show that some degree of moderation becomes necessary, and that although root-pruning is correct in principle, yet it may be prejudiced in rash hands. We always deem it expedient, therefore, to apply a mulching to espalier or trained Apples immediately on the heels of the operation. This encourages surface roots, and prevents the too sudden operation of extreme drought, which, combined with root-pruning—the summer succeeding the operation—is almost sure to cause the tree to be infested with the spider, the scale, or what is as bad as either, that rusty-looking fungus on the leaf, which if not checked may soon break up the constitution of the tree. We have had much experience of this last enemy, to which light and hot soils are peculiarly liable, and the only cure for it, as far as our experience goes, is a permanency of moisture at the root.—N.

HEDGE PLANTS.

(Continued from page 463.)

COLLETIA HORRIDA.

I WILL now glance at another plant, not, I fear, plentiful enough to form hedges to any great extent, but I will ask, Has anyone used *Colletia horrida* for that purpose, for which its touch-me-not character would seem to fit it well? I believe it to be sufficiently hardy for most situations that are tolerably dry, and it is not so shy a grower as some plants are. It certainly has not the fault of growing so late in the autumn as not to ripen the ends of the shoots; for the growth being moderate and the habit good, it seems well adapted for a hedge or fence almost without training or pruning of any kind, and the shoots being always of a rich green hue, the appearance must be good. I should certainly think it must make a sturdy fence, as every bit of it is pointed, and I should say as difficult to approach by man or beast as any plant I know, unless it be some of the Cactus tribe. Furze has no chance with it in keeping out intruders.

COLLETIA CRUCIATA.

This is not a less interesting object for hedge culture. It differs widely from the above, but its spines are scarcely less formidable. The plant, I imagine, is also much less hardy, and of slower growth: it may be advantageously grown for its curious character, and its white flowers are likewise attractive, being in some seasons produced in great abundance; it is not yet plentiful enough to become a competitor with other plants to form hedges, although its habit and appearance entitle it to notice.

It is not intended in this article to enumerate all the numerous plants used for hedges. The most common are Holly, Yew, Box, Arbor-Vitæ, Privet (both alone and mixed with other plants), several Cypressess, Laurels, and the like. The term fence cannot well be applied to many of these, although they make highly

ornamental hedges, but I believe that *Berberis Darwini* might be advantageously tried for the former purpose; it is of sturdy growth, and if sheep and cattle could only be prevented eating it, it would quickly become a strong fence. Another useful *Berberis*, however, is *B. Wallichii*, and both make excellent ornamental evergreen hedges. The *Aucuba* is, perhaps, as easily kept in order as any evergreen shrub, and amongst ornamental deciduous plants the *Fuchsia* ranks high; but a good hedge may also be formed of the deciduous kinds of *Berberis*, of which the common one is, perhaps, the best, at the same time I fear its beauty will be sadly marred when subjected to the close trimming that hedges have to undergo.—J.

AMERICAN TUBEROSES AS WINTER FLOWERING PLANTS.

So greatly prized are these deliciously scented flowers for cutting purposes that their pearly white blossoms are welcomed at all seasons of the year; but more especially is this the case at the present time, when choice sweet-scented white flowers are as a rule not very abundant. We have generally grown a good number for flowering during the summer

begun to shoot the sooner they are potted the better. It is important that all side growths be removed as soon as they appear, or they will speedily rob the embryo flower spike, and in many cases prevent the plant flowering at all.—H. DUNKIN.

GOOD VEGETABLES.

As the time will soon arrive when the seed catalogues will be coming in, it is best to be ready to order seeds as soon as the catalogues arrive, as it not only gives the seedsman more time, but you can depend on getting what you order, which you cannot always do later in the season. I know that old hands do not require other people's selections; although, speaking for myself, who am not a very young one, I like to see other people's selections. But I know the first few years I had my seed order to send I was very glad of any hints given in the Journal. There are so many varieties in the catalogues, they are simply bewildering to the beginner.

Broad Beans.—Early Mazagan is a trifle the best for the first sowing, as it is a little the hardiest; but the advantage is slight, and the beans are very small. I make a sowing of this in November, but rely on Early Longpod for general crop for sowing when the weather is fit the end of January. This is followed by Green Windsor. The large-

FIG. 71.—COVENT GARDEN MARKET IN 1745. (See page 545.)

months, but this season some plants are flowering later than usual, and judging by their present appearance seem likely to supply a few blooms continually for some months to come. Some of the plants are daily developing good blooms, others are swelling up their buds, and some are just showing their flower spikes. Early in the spring we commence potting the bulbs in 3-inch pots, taking care to first remove all side shoots. As soon as roots are plentiful the plants are shifted into 5 and 6-inch pots according to their strength, using a simple compost of two parts loam to one of sifted horse droppings. These plants are then grown in a vinery at work till the flowers begin to unfold, when they are removed to the conservatory or intermediate house. From the time the first bulbs are potted others are potted to succeed them at regular intervals of two or three weeks till the allotted stock is used up. In this way we have hitherto easily maintained a regular supply of these much-esteemed flowers till October, by which time most of our plants have in previous years finished flowering, with the exception of a few that showed no sign of a flower spike. These, if taken care of and placed in a warm house, will generally flower early in the spring.

This season our latest were potted later than usual. I am not quite certain about the exact date, having made no note of it at the time, but if my memory serves me rightly the greater part of our plants that are now growing or throwing up flower spikes were potted early in July; and considering how useful they are at this time of the year it is doubtless a good plan to defer the potting up of a good number of bulbs as long as it is safe to do so, though of course when once the bulbs have

podded sorts are not so productive for table use. Dwarf French Beans.—Ne Plus Ultra I find is the best for forcing and sowing in frames, also for first sowing out of doors. Negro is a good one to sow with it, and comes in after the other is over. Runners.—I do not find the new varieties more productive than the old Scarlet.

Beetroot.—A little of the Egyptian Turnip rooted should be sown for early use. Cattell's Dwarf is good for general crop. Where Spinach is in constant demand the Spinach Beet is an excellent substitute, or to mix with Spinach when you run short; and it will sometimes stand through the greater part of the winter. I do not find cooks take readily to the Seakale Beet. Grow some by all means if they will use it, as it makes a dish when something fresh is wanted.

Broccoli.—Walcheren is excellent for early autumn. The Cape Broccoli are often recommended, but I never found them of much service. I find Veitch's Self-protecting the most reliable one to succeed Walcheren, followed by Snow's White, Osborne's White, Cattell's Eclipse, Veitch's Model, or Sutton's Late Queen.

Brussels Sprouts.—Sutton's Exhibition for early, followed by Veitch's Paragon.

Cabbage.—Heartwell, Myatt's Offenham, or Mein's No. 1 are good selections; Rosette Colwort for winter use and Blood Red for pickling. Cauliflower.—Early Snowball, King of the Cauliflowers, are good selections of Early London, while Veitch's Autumn Giant is indispensable.

Carrot.—French Forcing is the best for frames. Early Shorthorn for sowing outside to come in before the large sorts, of which the Long

Surrey is good; but Intermediate is best where the soil is shallow. In gardens where the Carrot crop is often a failure I have sometimes found them succeed in a poorer piece of ground outside. I have always had good crops of Carrots since I took to rolling or treading the ground

Dwarf for white. Chicory.—The Witloef. Cucumber.—Telegraph. Endive.—Improved Batavian and Digswell Prize. Leek.—The Lyon.

Lettuce.—Tom Thumb is useful of the Cabbage varieties. If a larger one is wanted Neapolitan is good. Most seedsmen have a superb White

FIG. 72.—COVENT GARDEN MARKET IN 1889. (See page 545.)

well before sowing. What thinning is necessary is done as soon after they are up as possible, so as not to disturb the ground, as pulling them up does when they are larger.

Celery.—In my opinion Major Clarke's is the best, Sandringham

Cos of their own, which is often an improvement of Paris White, but sometimes the improvement is only in the price per packet. Hicks' Hardy White is the best for winter.

Onion.—This is another crop I make the ground very solid for when

sowing. I sow thinly, and if too thick I draw when very young and transplant. These often make the best Onions. Since I have adopted this plan I have not suffered so much with the grub. Does the system prevent it? Good sorts are Bedfordshire Champion, Danver's Yellow, James' Keeping, Red Italian Tripoli for winter, and The Queen.

Melons.—Blenheim Orange is a good scarlet, Eastnor Castle a good greenflesh.

Parsnip The Student.—To the beginner, perhaps this is the most difficult class, there are so many varieties (or rather names) to select from, and, in many cases, those that are highly recommended are the least profitable to the gardener. Many of those fine large podded sorts which are grown for exhibition are not good croppers. The best sorts for the gardener to grow are those with good flavour and good croppers. If they have large pods so much the better. Perhaps Telegraph is the most productive of the large podded sorts, but I consider Ne Plus Ultra the best gardener's Pea, combining as it does quality with quantity, and a continual bearer. But some of the improved Ne Plus Ultras are not such good and continual bearers as the original type. If I were confined to three sorts only, I should grow William I., Telegraph, and Ne Plus Ultra, but as I am not confined to so small a number I will add a few more. William I., Prince of Wales, Telegraph, Hundredfold, and Ne Plus Ultra.

Savoy.—I do not know one to equal Gilbert's Universal Savoy.

Spinach.—Sutton's Longstanding is the best I have tried for summer use, as it does not run to seed nearly as soon as the ordinary sort. The Prickly is the best for winter.

Tomatoes.—Hackwood Park Prolific.

Turnip.—Early Milan is the earliest, but it is not very good flavour; Early Snowball, and Veitch's Red Globe.

Pitatoes.—Rivers' Royal Ashleaf, Sutton's Early Regent, Beauty of Hebron, and Scotch Champion.—J. L. B.

NOTES ON CAMELLIAS.

THE Camellia is one of the easiest to grow of all hardwooded greenhouse or conservatory plants. Heaths and Azaleas are not so readily managed successfully, and they are also more difficult to restore to good health when allowed to lapse into a bad state. I am therefore greatly in favour of amateurs and growers of limited experience giving attention to Camellias. We have been cutting Camellias since the beginning of November, and there are still many buds to expand, but we do not think that Camellias generally—ours amongst the number—have been so good as in many previous seasons. The flowers have been more backward in opening, and they lacked their usual vigour. We attribute this to the deficiency of sunshine and maturing weather experienced during the whole of the time the wood and buds were developing, and if we thought that the coming season was to be as dull and backward, we should urge our plants into earlier growth than usual, that they might have a longer period in the autumn to gain a vigorous condition. By vigorous flowering condition I do not mean luxuriant growth and nothing more. Indeed I am never particularly anxious to secure undue luxuriance, as some of our plants which are most rampant are the least floriferous. A moderate growth, well matured, is far before great luxuriance in producing and retaining a profusion of buds and opening well formed blossoms. I put considerable stress on the word "retaining" as used above, because many Camellias may be grown rapidly to produce a great number of buds; but how many of these fall prematurely? This is attributed to various causes—excessive dryness at the root, and too much heat in the atmosphere; but buds that are well matured will pass through many vicissitudes.

It is immediately after flowering that mistakes ought to be rectified, and everything placed on a better footing, if such is wanted, for another year. Pruning is an operation which scraggy little plants in pots seldom call for, but it is a necessity with many planted-out specimens, as well as those in pots and tubs, that have become too large to be accommodated under glass. Healthy plants will bear pruning as well as a Privet, but it is a mistake to prune and cut back sickly specimens, unless it be to repot them, cut them hard in, and start them into growth sharply in a forcing pit. Those that are planted out and doing well in beds and borders are apt to push out until they obstruct the pathways, and to prevent this they should be cut back before growth is far advanced, but this should not be done in such a manner as to make them appear as if they had been clipped like a hedge. A flat surface on a Camellia is never graceful, and if they are cut in merely to avoid the path, and nothing more, the blooms that come out on the edge will be sure to be brushed and injured. The better way is to cut them back some little distance from the path, that they may have clear headway for a few years, and if the forward branches are cut out, and those in the background allowed to remain, there will be no appearance of a clipped surface. The same rule applies to cases of cutting them down when they are too near the glass. Often before the last of the blooms have expanded the young shoots have pushed forth several inches, but this should not deter anyone from pruning, as it will not prevent the plants growing freely on the old wood that remains.

During the time Camellias are in flower they cannot be syringed or washed without injuring the blooms, and it is best to keep water from the foliage then; but immediately flowering is over they should be thoroughly cleansed. If the leaves are only dusty syringing will generally suffice, but where insects exist the leaves must be well sponged. The time to do this is immediately pruning is over, and before the young growth is advanced; but healthy plants have a great power of resist-

ing insects, and their deep green glossy leaves are very pleasing. It is at the end of the flowering season that repotting or planting should be done. They do not like overpotting. Neat little bushes may be secured in 7-inch and 8-inch pots, and large plants in 10-inch and 12-inch pots. An additional root space of 2 or 3 inches at a time is ample. Perfect drainage is most desirable, and a soil consisting of half peat and half loam, to which a liberal dash of sand or grit has been added, will prove a satisfactory rooting compost. In potting or planting in any form the soil cannot be made too firm about the roots, as the roots soon take possession of a firm soil, and remain healthy in it. If Camellias are well planted out they invariably give much satisfaction, and they are less trouble than when in pots and boxes. There ought to be more of them in beds and borders, but those who contemplate turning them out should be warned against one rather common practice. It is this. Plants that are in bad health in pots may be regarded as hopeless are thought sufficiently good to plant out, with the avowed object of restoring them. This is a mistake, as if they cannot be revived in pots they never will in beds, and failure will be the rule in cases of planting out half-dead specimens. There are only two kind of bushes we recommend being planted out—one is healthy young plants, the other overgrown specimens, and with both of these excellent results may be secured. Bushes that are long and shy in starting into growth should be freely watered with soot liquid, and they should be syringed freely twice on all bright days, moisture in abundance being applied to the tops and roots of all plants disposed to grow rapidly.—M. M.

PALMS.

AMONG the numerous plants now cultivated for the embellishment of the interior of the homes of England, Palms are most useful. Their bold outlines, diversified forms, and graceful habit always command attention, as well as serving to show to greater advantage the colours of the flowering plants associated with them. Another great point in their favour is, that with careful attention in the matter of watering, and sponging the leaves occasionally with soapy water, the same plants will often thrive for months together in the drawing-room almost as well as in glass structures. I do not mean to say that this is the case with all Palms, as unfortunately some of the most beautiful, such for instance as *Cocos Weddelliana* and *Geonoma gracilis*, require to be changed frequently to prevent their falling into an unhealthy state. Happily there are many others of striking and varied beauty that can be depended upon to keep in robust health for a long time when used for house decoration.

An important point in their management which must not be overlooked is, to take each plant out of the vase in which they stand once every two or three weeks, wash the vases, and after replacing the plants cover the surface of the soil and pots with fresh moss. If this matter is not regularly attended to the water that passes through the soil and settles at the bottom of the vase in time becomes sour and unwholesome, and in not a few instances has been the cause of plants used for house decoration getting into an unhealthy state much sooner than they otherwise would do.

Those enumerated below are all reliable Palms for the purpose indicated, and collectively they supply great variety in the form of their fronds and in their habit of growth. *Areca Baueri*, *A. lutescens*, *A. sapida*, *A. crinita*, *A. Verschaffelti*, *Caryota sobolifera*, *Chamædorea elegans*, *glaucochylla*, *Chamærops excelsa*, *C. humilis*, *Cocos plumosa*, *Euterpe edulis*, *Kentia australis*, *K. Belmoreana*, *K. Fosteriana*, *Latania borbonica*, *Phoenix dactylifera*, *P. reclinata*, *P. rupicola*, *Thrinax elegans*.—H. DUNKIN.

MUSHROOM BED REFUSE.

HAVING a considerable quantity on hand and a good run of beds laid down this season, I am anxious to see how to turn the material to account in the cultivation of other crops for market, for which this manure would be well adapted.

Mr. Barter advised me to get a few acres of land and use up what I could not sell. What, then, would be suitable crops in rotation through the year?

I find a prejudice exists against the material "as used up" and "only good for potting." I tried it with French Beans this summer in the open, the result was a splendid crop; also I transplanted some Jerusalem Artichokes so advanced in growth that I expected, if they survived, to find nothing but stem and leaf growth. This was vigorous, but to my surprise the tubers are grand also, far surpassing the others. They had a liberal dressing.

I have had several analyses made, which do not bear out the misnomer "spent bed;" spent only so far as concerns the bed's capacity to produce Mushrooms, which evidently rob it but little of its original manure wealth. This seems to remain on hand, presenting the needful plant food in a more concentrated form. The analyses I have give over 1½ per cent. ammonia and 2 to 2½ per cent. phosphate of lime, with water under 50 per cent. When calculated on the dry substance the ammonia and phosphate of lime are only slightly under that found in ordinary farmyard manure, while the amount of moisture is considerably less—just under 50 per cent. as against 75 per cent. Surely, therefore, there should be a good field for its use in the way indicated.—MUSHROOM.

[The material evidently suits the soil of our correspondent, and as it has proved so satisfactory for the crops mentioned it will be suitable

for others. It is excellent for early Potatoes, and full crops of these are profitable, while the land is relieved in time for successive crops of Turnips, Horn Carrots, Spinach, Lettuce, Endive, Coleworts, Cauli-flowers, and winter greens generally.]

THE NATIONAL CHRYSANTHEMUM SOCIETY.

THE annual dinner of the above Society, held at Anderton's Hotel, Fleet Street, on Thursday evening last, proved a success of a quite exceptional character, and one of the largest horticultural gatherings of the kind ever held in London. Over 170 members and visitors were present, the large hall on the basement of the Hotel being fully occupied. The five tables were tastefully decorated with plants, cut flowers, and fruits contributed by numerous friends of the Society, and some handsome Cordylines, Palms, &c., were supplied by Messrs. Laing & Sons for the adornment of the hall and staircase.

The President (Lord Brooke, M.P.) took the chair shortly after 6 P.M., and was supported by Sir Guyer Hunter, Sir Edwin Saunders, the Rev. W. Wilks, Capt. Molesworth, Mr. Shirley Hibberd, Mr. E. Sanderson, Mr. W. Johnson, Mr. McAllister, Mr. R. Ballantine, Mr. W. Lowles, Mr. W. Harland, and Mr. C. H. Pearson.

A long programme of toasts was provided, and the musical department, under the superintendence of Dr. Haskins, was a substantial addition to the enjoyment of the evening. The customary loyal toasts were proposed by the President in admirable terms, his remarks being received with loud applause. "The Continued Prosperity of the National Chrysanthemum Society" was next proposed from the chair, and Lord Brooke, in the course of an excellent speech, referred to the great advance that had been made in the culture of Chrysanthemums in recent years, and complimented British horticulturists on the success of their efforts. He thought, however, there was still one matter in which there was room for improvement, and that was in the odour of the blooms. He would like to see some sweet-scented varieties raised both for home use and exhibition, and he considered it a subject worthy the attention of those concerned in the improvement of the plant. As regards technical knowledge, he could not of course claim to equal many of those in the room, but he would yield to none in the love of plants and gardening generally, and he paid a graceful compliment to his gardener, Mr. Lister, when he said that much of the interest he felt in the subject was due to his efforts. The celebration of the Chrysanthemum Centenary next year was alluded to, and his lordship concluded with the expression of an earnest wish that the Society would continue its prosperous career.

An interesting ceremony was next performed—namely, the presentation of the medals and the challenge shield offered in competition to Chrysanthemum Societies throughout the kingdom. The first of the gold medals was presented to Mr. John Laing, who was followed by Mr. Henry Cannell and several others; and on behalf of the Wimbledon Society, which had won the challenge shield, Mr. Gibson, who represented the Society named in the competition, was appointed to receive it, and convey it to the successful Society for the year. The Hon. Secretary then announced that the whole of the prizes awarded at the November Show had been received by the winners, the money prizes having been forwarded by letter.

In replying for the prizewinners Mr. J. Laing said that he was a grower of Chrysanthemums forty years ago, and mentioned that the only variety then grown and still included in collections was Queen of England. Mr. Gibson also replied briefly and to the point.

The health of the President was proposed by Mr. Jukes and responded to by Lord Brooke, many other toasts following, and a centenary prize fund being opened a substantial amount was received before the close of the proceedings.

CUTTING DOWN CHRYSANTHEMUMS, &c.

I WAS pleased to see the note by "J. L. B." in last week's Journal under the above heading, as it opens up an important subject, and at an opportune time, touching as it does upon the two important matters—When is the best time to propagate? and topping to induce timely bud formation. So far as my knowledge and observation goes the latter practice is annually growing in popularity and general adoption amongst northern growers, at least with a very many varieties of Japanese.

I also am of opinion that the first question, relating to propagation, is of equal importance as regards obtaining the best bud at the right time as is that of topping. I have practised the latter for several years and closely watched its effects and results.

For those two late incurved, Eve and Mabel Ward, I found that propagation early in December and topping the first week in May had the desired effect. Meg Merrilies and its sports, Boule d'Or, Duchess of Albany (Jackson), Mr. H. Cannell, Mrs. H. Canuell, Gloriosum, Pelican, and other such late Japanese propagated late in December and topped middle of May came at the right time.

Thence onwards each week, throughout May, June, and to the first week in July, I have continued to top a few, taking into consideration their relative earliness and the condition of the plants at the time, those first topped being of course done with the object of hastening bud formation by inducing an earlier break than would accrue by waiting for the natural break, those topped so late as July being early comers, as Comte de Germiny, Edwin Molyneux, Baronne de Prailly, Fredk. Marrouch, Gorgeous, &c., and amongst which will, I believe, have to be included Laing's fine new variety Stanstead Surprise. These being topped after the July bud had formed and the first breaks commenced growing, taking these clear away, and causing the buds lower down to start and form breaks, thus retarding the plants at least a fortnight. The Teck family are not, I think, benefited by topping, and should be propagated not later than December. Nor do I think topping to be advantageous to the Queen family, providing they are propagated at the right time, and this I believe to be towards the end of January. I hope some of our northern friends will continue this discussion. What say our friends Messrs. Udale and Garnett? They have for some years past experimented and studied this matter closely, and can speak with the force of experience. Mr. Morton, too, of Darlington, whose knowledge of Chrysanthemums and their culture is second to few, tells me he cannot possibly induce his buds to appear generally at the right time only by this system of topping.—W. K. W.

GROUPING CHRYSANTHEMUMS AT SHOWS.

COMMENTING upon the remarks by Mr. Castle at page 479, Mr. Brown is desirous that Chrysanthemum committees should endeavour to fortify themselves against errors and complaints by making the wording of their schedules more explicit and clear before issuing their particulars for the next season's guidance. It generally happens that committees entrusted with the management of the different Chrysanthemum Societies throughout the country are usually aware of the circumstances best suited to the requirements of their own localities. In order to secure good local competition their schedules are compiled and worded in a manner best calculated to meet the individual necessities of local exhibitors, with open classes added, the wording of which is generally explicit and clear and based upon broad principles. With regard to grouping, the principal topic for argument, doubtless much misapprehension exists, although nothing can be more objectionable, as remarked by Mr. Castle, than an array of bare stems and stakes around the base of these purely Chrysanthemum groups; but when one is supported by the fact that groups of this nature can be made more effective by bringing the Chrysanthemum flowers and foliage to within 9 inches of the floor level, surely there is something to encourage the enterprising exhibitor to exercise his abilities, and endeavour to remove the objections at present existing against groups of this class. The next principle of grouping, as mentioned by Mr. Brown, is the same as adopted by the Hull and East Riding Chrysanthemum Society, and is beyond question a more artistic arrangement, and when the schedules stipulate, as in their case, a group of Chrysanthemums with foliage plants interspersed and arranged for effect in a space of 100 square feet, surely nothing can be clearer.

As to the extent foliage plants should be used in the arrangement of such groups, it rests entirely with the exhibitor's capabilities of knowing when he has produced the desired effect, quality depending solely upon the materials employed. Mr. Castle suggests a more artistic arrangement might be produced by a more extensive use of Ferns, Palms, and other decorative plants, with a few Chrysanthemums dotted in to give the whole effect. That such an arrangement would merit appreciation no one would attempt to deny; but a system of miscellaneous grouping at Chrysanthemum exhibitions would have some disadvantages. Valuable plants would be required in the arrangement, and when we consider the unpropitious nature of the weather during November there would be some risk of loss at a time when the decorative requirements at home demand great attention.—J. P. LEADBETTER, *The Gardens, Tranby Croft, Hull*.

AQUARIUM NOTES.

"ARE you going to write a report?" was the question put to me by a friend the other evening. "No," was my reply; there are those connected with the staff of the Journal who can do it so much better than I did not even venture to suggest it; but although I did not write a report I can give a few notes, for I grow some (not for exhibition), and endeavour to keep up my acquaintance with the new sorts, and the progress and well-being of the Chrysanthemum. There may be nothing in these notes—if so, I must apologise for inflicting them on the readers of the Journal.

I suppose it is pretty generally agreed that so far as cut blooms were concerned the Exhibition was not equal to those of former years; but, on the other hand, the groups of plants in pots were excellent. I do not think that I have ever seen one equal in point of merit to that set up by Messrs. Laing & Son of Forest Hill. There was an excellent mixture of Japanese and incurved varieties; the colours were exceedingly well mixed, the foliage very full and fresh, and the plants well furnished at the bottom; there was not an excess of training, and altogether it was a most delightful group. In some of the classes there was a painful excess of training, a practice which I think the National would do well to discourage. The Chrysanthemum is not an ungainly plant, and it cannot do without some support; but why should it be contorted and twisted so as to form an umbrella, a mop, or anything else? and yet that is what was to be seen at this Exhibition, and indeed at most

exhibitions where the Chrysanthemum forms the main, sometimes the sole feature. I remember when this excessive training was the rage for Azaleas, but at last people rebelled, and although they appear in fair numbers, yet the collections of huge extinguishers covered with bloom no longer attracts, but rather repels the public.

In looking at both the incurved and Japanese cut blooms I grieve to find in both two great errors. First of all the running upon size. It pervades everything in horticulture nowadays—big Grapes, big Cauli-flowers, big Onions, &c. Nothing is valued now unless it has size; the larger the better seems to be the motto of present day cultivators. But see what is lost. There was, for instance, that monster Etoile de Lyon a foot in diameter, but a coarse flower, which had indeed a good deal of the Etoile about it, but no beauty; its coarseness destroyed all interest in it. The other error is the dressing of the flowers. I have in my day taken part in many a stand-up fight on this subject. I have deplored it in the case of the Carnation and Picotee, but I got nothing for my pains, and now as then the success of an exhibitor depends not so much on the excellence of his culture of the flowers as on the skill of the dresser. This is applied not only to the incurved varieties, but to the Japs also, especially to such flowers as Comte de Germiny and others of that style. I do not think that it is at all necessary to do this. I have blooms of Mr. H. Cannell and Mrs. H. Cannell which have never been touched with tweezers, and yet they fold gracefully into the centre, and I am quite sure if I were to attempt the dressing I should do more harm than good.

I know that all this is very much like "crying in the wilderness." People will go on trying to get big flowers, and spending hours over the manipulation of their blooms. They do not, it is true, as far as I know, attempt to alter the character of the flowers, not, as it were, to turn a cupped into an imbricated flower, and an incurved flower remains an incurved flower still, but immense pains are taken to hide any defect and to make the flower as symmetrical as possible.

Of course when new varieties are spoken of, the first question was, Have you seen Mrs. Alpheus Hardy? and a general pilgrimage took place to St. Stephen's Hall, where the introducer had staged half a dozen blooms. In everything except size the plates and descriptions of it were not exaggerated. It is really a most beautiful and curious flower, valuable not only in itself, but as probably the forerunner of a new departure in Japanese. Already we are told that there is a pink variety of the same strange character. Whether it will ever be an exhibition flower depends on circumstances. It has no doubt been hurried on into growth for sale purposes, and like our newly introduced Roses we cannot tell much about it for a couple of years, but if it grows at all well, and the plant exhibited leads one to hope it will, it will be a general favourite. Of other new varieties the following were noticeable:—

Mrs. Falconer Jameson.—Very large blooms of chestnut tinge, shaded with yellow, very fine.

Avalanche.—This is a very beautiful and most useful flower, and its excellence was shown by the fact that all the prizes for six white Chrysanthemums were taken by it. It is of the purest white, large and well formed, the plant is vigorous, and the flowers are very freely produced.

Sunflower is, as its name imports, a large bright yellow flower, very massive.

Of flowers not quite so new there were good examples of Edwin Molyncux, Mr. H. Cannell, Mrs. H. Cannell, Mrs. J. Wright, Sarah Owen; and, indeed, I suppose they have found places in most collections, for the Chrysanthemum is so easily propagated that a new variety is not long in finding its way anywhere.

Amongst the miscellaneous exhibits, two Pelargoniums exhibited by Messrs. Cannell & Sons particularly struck me: one was Souvenir de Miranda, of a lovely shade of salmon and pink; and Richard Dean, a dark purplish crimson. They were exhibited in that perfection which even in winter he is able to attain.—D., Deal.

RUGBY CHRYSANTHEMUM SOCIETY.

THE annual meeting of this Society was held on Wednesday night, December 18th. L. Cumming, Esq., M.A., was unanimously elected Chairman for the evening. After a few introductory remarks he called upon the Secretary (Mr. W. Bryant) to read the Committee's report and balance-sheet for the year. The report stated that the number of subscribers to the Society is 188, a slight increase upon the number of members for the preceding year; and the balance-sheet also showed a rather better, although still a small, balance in the hands of the Society. In thanking Mr. L. Cumming for his admirable lecture upon "The Reason Why in Horticulture," the Committee hoped to obtain other members to help by giving lectures or reading papers, so that the preamble of the Society might be more fully carried out. The balance-sheet showed the total amount of receipts at £101 11s. 2d., and the expenditure at £95 12s. 8d., leaving a balance of £5 18s. 6d. upon the year's work. The Secretary in a few remarks pointed out that the money paid in prizes and specials amounted to £54, or exactly £1 7s. 6d. less than the list of subscriptions, showing that to meet the expenses of the Society it really depended upon the door money. He then went on to advocate the necessity of the Committee making the prices of admission as popular as they possibly could, and gave statistics of the number of persons paying at the different prices during the late two-days Show, which was rather interesting, as indicating that committees should provide for the masses. On the first day, from one to four o'clock, the price being 2s. 6d., only eleven paid at door; during the 1s. time, for both

days, 126 paid; during the 6d. time, for both days, 748 paid; and on the last evening, from six to half-past nine o'clock, the admission being 3d., no less than 925 (or more than half the total number) paid at door; the number of visitors to Show, including subscribers, being 2212. The Chairman then gave an interesting and instructive review of the Society's work, and was followed by Messrs. T. M. Wratishaw, W. Phillips, and others.

The date of Show for 1889, after a very animated discussion, was fixed for November 12th and 13th, many present considering it inadvisable to clash with Birmingham, a coincidence we should certainly say is regrettable and injurious to both societies, but more especially to the younger one.

GAY FLOWER BEDS IN SPRING.

I DO not know any plant or bulb that can surpass the homely Crocus for effect in the early spring when cheapness and durability are taken into account. In starting to plant Crocuses in the flower beds trench the ground thoroughly, and in the process incorporate 5 or 6 inches of good manure; also well break up the subsoil. Do not by any means bring any of the crude soil to the surface. If the staple soil be strong incorporate sweepings of walks, burnt refuse, old potting soil, old mortar, or even fine coal ashes, if nothing better can be had, as the Crocus is rather partial to an open soil. After the beds have been trenched it is a good plan to fork them, to assist in working the soil down more firmly; then run over the beds after forking with the garden rake, to work them into form for planting, the same as would be done for May bedding plants. Make the rows from 1 foot to 18 inches apart. Plant the clumps about the same distance from each other in the rows. If the beds are a geometrical group corresponding beds may be planted with corresponding colours, the same as bedding plants. Self colours of Crocuses make the best show. After the lines are marked out for planting place ten to twenty bulbs in a clump 8 or 9 inches deep, the bulbs half to 1 inch apart. It is well known that the Crocus makes a new bulb every year on the top of the old one, which helps to bring them nearer the surface. After planting rake the beds, then apply some short decayed manure, and bury it with the spade 1 or 2 inches deep. Some people might think that they would never see their Crocuses again after planting so deeply, but if the ground be in good order the grass or leaves of Crocuses will make appearance in due season. After the first year they will come up very fine, and well repay the trouble taken in planting. With care in planting and taking up bedding plants the Crocuses could remain without removal for eight or ten years. If the beds are given 2 inches of short manure every autumn after the bedding plants are removed that will be about all the care or cost they will require. A few good varieties are Fleur d'Or, Golden Yellow, Queen of Sheba, large yellow; Garibaldi, extra large purple; King of the Blues, fine purple; Marie Stuart, fine white; Mont Blanc, grand white; Queen Victoria, pure white; Van Speyk, beautiful violet and white striped.—DISENGAGED.

THE BULB MITE.

HAVING tried a very simple remedy for the destruction of the mite on various bulbs, and with good reason to be satisfied with the result, I beg permission to make it known through the pages of the Journal for the benefit of others who may be pested with the mite. I have not heard if such a simple method has been tried before, but if it has I should be glad to hear with what result. Previous to describing the method I adopted I wish to make a few remarks concerning the mite, and the various opinions expressed on the matter. Various causes are credited with the destruction of so many bulbs, especially the Eucharis, which appears to suffer most from the evil, caused, in my opinion, by the mite. But the Eucharis is not the only bulb affected; Pancratiums, Vallotas, and Amaryllises are also subject to its attacks. It is asserted that bad cultivation, over-watering, and checks being given the plants cause the mite to appear, and I have heard it stated that spontaneously with the decay of any matter insects will appear upon the scene. That I do not wish to dispute; but it is my opinion that the mite appears before decay take place, and that they prefer the young healthy roots to any decaying matter. If it was the decaying matter only they feasted upon cultivators would not begrudge them that. They appear to me to confine their operations chiefly to the roots, eating the tissues of the roots and leaving only the skin, making them like so many straws, and as fast as young roots appear so they share the same fate, until the vitality of the bulb is greatly impaired and it ultimately decays. As regards watering being the cause of the collapse of the Eucharis, I cannot believe that over-watering will harm them. When we consider that the Eucharis is a semi-aquatic plant, and will thrive growing in water, I think we must expel that idea from our minds. I have had them growing in a tank of water the greater portion of the summer without any harm to them; on the contrary, they were perfectly healthy, and at that time I did not know what the mite was, and it was that treatment that has since suggested itself to me the method I have adopted in dealing with the mite.

Last spring, having most of our Eucharises in a bad state, I had them placed in water, covering the leaves and pots with water, and left them for a day and a night. After they were taken out and the soil drained a little, the soil was shaken from them and the dead roots cut away, they were placed into fresh cut turf and leaf soil, which had previously been subjected to the heat of a newly turned heap of stable

manure for a couple of days, and then returned to a good temperature, where they soon filled their pots with roots, and are now as healthy both in root and foliage as one would desire, and nearly every bulb has flowered. They had abundance of water as soon as the roots got to the sides of the pots. Having no means of baking the soil, a hint received from the Journal, I followed what I considered the better plan of the two, in subjecting it to the heat of the manure heap, which also materially enriched it. Anyone having any suspicion of mite about their bulbs should try this plan.—W. SIMPSON, *Knowsley*.

DRESSING ROSE BLOOMS.

FROM the report of the annual meeting of the National Rose Society, which meeting I was unable to attend, it appears that another clause was added to section 8 of the "Regulations for Exhibitors." The section now runs thus: "All Roses must be exhibited as cut from the plants. Artificial aid of any and every kind is strictly prohibited, with the exception of wire or other supports, which are to be used only to keep the blooms erect. Dressing Roses so as to alter their character is also prohibited, also the insertion of any additional foliage." May I be permitted to offer a few remarks upon the clause which relates to the dressing of Roses?

I presume the term "dressing," as here applied means the manipulation of the bloom by the exhibitor in order to present it in its most perfect form, in his opinion, before the eye of the Judges. This result, however, may, or may not be attained.

Someone may say dressing never used to be heard of in connection with the queen of flowers, can it be necessary now? Yes, in my humble opinion it is in many cases quite necessary; for of many sorts, especially of the newer varieties, introduced within the last fifteen years, the robustness of the plants and the size of the blooms, together with hard pruning, thinning, and disbudding, have caused the flowers in several instances to be unable to develop themselves to their utmost capacity unless they have a little assistance. Dressing is practised by some of our exhibitors, and those not the least successful, and the man who neglects it does so at his peril.

Now with reference to the words, "so as to alter their character." Dressing is by this clause officially recognised. It is not as a practice that it is condemned, but only when we come to the result of dressing that pains and penalties threaten us. If the character of the Rose is preserved all is well; if, on the other hand, the character is altered or the bloom spoiled, disqualification is to be the punishment. But before this disqualification can be made, two points must be clearly proved—First, that the Rose is out of character; second, that this loss of character is the result of dressing. With regard to the first point take *Souvenir de la Malmaison* for an example, and consider in how many forms she presents herself—the flat, the cupped, and the globular high centre; or how variable the shape of *Beauty of Waltham*, sometimes like *Alfred Colomb*, *Marie Baumann*, or *Benoit Comte*. I venture to say it would be difficult to decide positively that a certain Rose is out of character. But suppose you have found such a bloom, you have next to decide the second point, that this alteration of character is the result of dressing. This you have to prove, but on what evidence? If you are a judge you have no right to stand by and watch the staging of exhibits you are soon to judge. How are you to obtain conclusive evidence that this particular bloom in question has been dressed?

Now I come to the worst part of the whole case. This question, as I understand it, does not rest solely with the judges, their decision is final only with reference to duplicates—see rule ix. The disqualification can be made at any time before or after the awards have been made by three members of the Committee, even after the exhibitor himself has gone home to prepare for the next show, and so unable to defend himself. I much regret that this clause, so difficult to carry out, has been added to our rules, more especially as it is unaccompanied by the necessary safeguard to all peace and goodwill, that the judges' decision shall be final.—JOSEPH H. PEMBERTON.

TWO GOOD LATE FLOWERING ROSES.

LA FRANCE amongst the bushes and *Souvenir de la Malmaison* amongst the climbing sorts are the two most prolific late flowering sorts I have any experience of. Both are pale in colour, both bloom so profusely as hardly to form sufficient wood to extend them. They are grand blooms, delightfully fragrant, and all who desire to have many Rose blossoms in perfection in October or even November should grow both.—B.

MANNERS AND CUSTOMS—A CATALOGUE COMMENTARY.

(Continued from page 530.)

Dr. Andry (Verdier, 1864).—Of capital growth and foliage, not much injured by mildew or rain, almost always comes well formed, imbricated with a point, early, of good size, good in petal, centre, and colour; lasts fairly well in shape, but not so well in colour; very free-

flowering, a row of it making a grand show for a few days, but not so good as an autumnal; a useful and thoroughly reliable Rose of strong constitution, which will do fairly in weak soil.

Dr. Sewell (Turner, 1879).—Rather weak in growth and foliage, liable to mildew and to burn, but not much injured by rain. Does not often come thoroughly good, but when it does is a fine distinct dark Rose of good shape and size, but not of high quality as a free bloomer or autumnal.

Duchesse de Caylus (Verdier, 1864).—See *Penelope Mayo*.

Duchesse de Morny (Verdier, 1863).—Of fair growth and foliage in good soil, the wood and leaves being very distinct and characteristic. Liable to mildew, but will stand some rain. The blooms come well shaped with very smooth stout petals, beautifully full, of distinct and lovely colour, large size, and fair lasting qualities. This Rose is one of the very smoothest and regular in globular imbricated shape that we have; a free bloomer, but not so good in autumn, and rather dainty as to soil and treatment. The shoots often come wholly or partially fasciated—i.e., laterally jointed together, either for a short distance or right up to the bud, and the buds should be well thinned, for this is one of the sorts where no fear of coarseness need be entertained.

Duchesse de Vallambrosa (Schwartz, 1875).—Of very strong distinct growth and foliage if it does well, but will not thrive everywhere. Not very liable to mildew, but cannot stand rain at all, and being of a very light colour may be injured by thrips in a dry season. The blooms have a decided tendency to come badly shaped, often with me having a gap or chasm in the outline, as if a wedge had been cut out. The shape is rather too open at the best, but it is of large size, fair in lasting qualities, and as an autumnal.

Duke of Edinburgh (Paul & Son, 1868).—Of strong good growth and foliage, with characteristic wood; the secondary shoots are very long, and rather spindly and pliable, so that the blooms are sometimes pendant. Not very liable to mildew, or much injured by rain. Generally comes true to its shape, which is good so long as it holds its point; but the petals are not very stout, or the centre very full, and it is not a good laster. Of full size and most brilliant colour, vermilion crimson. In strong specimens the crimson predominates when the bud shape is passed, but the self vermilion, which is generally found only on the weaker blooms, is perhaps the most effective. Not very lasting in shape or colour, but of large size, a free bloomer, and fair autumnal. This was for years the brightest of all red Roses. It was "The Duke" *par excellence*, as *Baroness Rothschild* was "The Baroness," though *Duke of Wellington*, not so bright, was of earlier introduction. A lady friend used always to pounce upon any red Rose in my garden that showed extra brilliance, saying that she knew what *that* Rose was—it was the *Duke of Edinburgh*. Of good hardy constitution, but rather apt to run to wood instead of to bloom, especially in autumn and on the *Manetti*.

Duke of Teck (Paul and Son, 1880).—Very like the last-named in most particulars. I do not know if there is any relationship; but different in colour, having much less of the dark crimson, and perhaps not quite so brilliant. The shape is also rather more globular and less pointed, but other manners and customs are the same.

Duke of Wellington (Granger, 1864) is marked in some catalogues as moderate—i.e., weakly—in growth, but is quite fair in vigour and foliage with me. Not very liable to mildew or much injured by rain, a free bloomer, and quite a good autumnal. The blooms come well in what I call the pointed form, and consider the finest shape of any. First class in petal and fullness, and grand in dark crimson colour and lasting qualities. Medium in size according to the N.R.S. catalogue, which I can quite believe to be the case where the growth is moderate, but well up to the average with me. Will not do in hungry soil or where not well treated, but high feeding and close pruning will generally produce splendid blooms. Older than the *Duke of Edinburgh*, and in spite of general repute, the best show Rose of the two with me. This is one of the Roses which close their petals in the evening, thus seriously disconcerting at times those exhibitors who have to choose their blooms at those hours.

Dupuy Jamain (Jamain, 1868).—Of very strong, stiff, stout growth and foliage, with vigorous clean smooth shoots, such as a Rose should have. Not liable to mildew, and but little injured by rain (I ought to say that almost all H.P.'s are sometimes attacked with mildew, except perhaps *Paul Neron* and *Ulrich Brunner*, and all are better without rain, so not liable must be generally taken as not specially liable). The round fat shoots of *Dupuy Jamain* produce round fat smooth blooms, which generally come well shaped, but the petals are not so stout as they look, and the centre is weak in hot weather. Of large size, but a bad laster; very free in bloom, and perhaps the best of all autumnals of its colour. If I wanted a red Rose at the end of October I should come here first, and if any H.P. will bloom at Christmas this will. A good and reliable cool season Rose, of strong hardy constitution, which will grow almost anywhere.

Earl of Dufferin (Dickson, 1887).—I have not had this Rose long enough to enable me to particularise its habitual manners and customs. I am afraid it has its little ways in requiring fine weather, and perhaps sometimes coming rough in outline, but it is not fair to speak of the habit of a variety till it has been tested during different seasons.

Edward Morreaux (Granger, 1868).—Of extra strong thorny growth, with rather rough foliage. Not liable to mildew, but being very full is very apt to be injured by rain. This is one of the coarse Roses, too full in petals, often badly shaped, and rarely symmetrically arranged. It

should be of the true globular shape, which is an exacting form where the bloom is so very double and full; but often the flowers come flat and open, more like Jules Margottin, from which it is a seedling. Very large, and a good luster; a free bloomer, but not a good autumnal. A big standard of this Rose in full bloom is a fine sight, and very effective, especially at a little distance. Very hardy, and of strong constitution.

Emilie Hausburg (Levet, 1868).—A weakish grower, with characteristic very green wood and foliage. Not much liable to mildew or to be injured by rain. The blooms come fairly well, but very late, generally too late for exhibition; of splendid globular imbricated shape, with good petals, but weak in the centre; good in lasting qualities and size, but by no means a free bloomer or a good autumnal. Thus this beautifully shaped and very distinct Rose is in a fair way to be discarded, being generally too late for exhibition and too shy in blooming and weak in growth to be useful for other purposes.

Etienne Levet (Levet, 1871).—Of robust and smooth but very uncertain growth; long, strong, and stout in rich soil, where it has a good hold, but otherwise quite short and stumpy. The foliage is very fine, and the blooms come well, with large, very smooth, shell-like petals; but the shape is open, the centre rather weak, and the form not lasting. Must be cut small for exhibition, and is not very reliable in hot weather. Not much injured by mildew or rain, but not good as a free bloomer or autumnal. Of large size, and its grand petals and smooth even outline make it an effective show Rose; but for general cultivation or on weak soils it is not one of the best.

Eugène Furst (Souper et Notting, 1875).—A very strong grower, with good foliage, liable to mildew, which appears even on the petals, but not much injured by rain. This is a Rose whose manner it is to waste all its strength upon the wood, and have none to spare to swell the bud. In H.P.'s and Teas we have some Roses which promise more than they perform, and others which perform more than they promise. Thus, in H.P.'s, this Rose has small blooms on very strong shoots, while François Michelin has very large blooms on thin small shoots. In Teas, the class of those who promise more than they perform finds exponents in Comtesse Riza du Parc, and (with me) Etoile de Lyon, while the good part of François Michelin is ably played by Comtesse de Nadaillac. Eugène Furst comes fairly well, of a good dark velvety colour and fair shape, lasting well. The blooms are late and not so numerous as they ought to be, though coming well again in the autumn; but it is an impostor, and wastes a quantity of good Rose nutriment on those sturdy, lazy, disappointing shoots.

Eugénie Verdier (Guillot, 1869).—See Marie Finger.

Exposition de Brie (Grainger, 1865).—See Ferdinand de Lesseps.

E. Y. Teas (Verdier, 1874).—Only moderate in growth, with fair foliage. Not much liable to mildew, and stands rain fairly. The blooms come well, very full, of compact, regular, smooth, globular shape, bright colour, and good lasting qualities, but decidedly below the average in size. Fairly free in bloom, but not much use as an autumnal.

Ferdinand de Lesseps (Verdier, 1869).—Synonyms, Exposition de Brie, 1865; Maurice Bernardin, 1861; and Sir Garnet Wolseley, 1875. This, though not the oldest, is probably the best known of the four declared by the N.R.S. to be identical. It is said that Sir G. Wolseley's lighter in colour than the others, but having given it up for several years I cannot now offer an opinion on the subject. Of good growth and foliage, rather liable to mildew, but not much injured by rain. The blooms come pretty well, of good globular shape and fair general qualities. This variety always seems to me to represent a fair average Crimson Rose, unusually free from peculiarities or special manners and customs.

Fisher Holmes (Verdier, 1865).—Of good growth and fair foliage. Particularly liable to mildew, but not much injured by rain. The blooms come well, of the good pointed shape of Duke of Wellington, which it slightly resembles. The N.R.S. catalogue speaks of it as "rather thin," but I have not found it so; on the contrary, with me the shape is lasting, though the brightness soon fades. Rather below the average size, but very free blooming, and a capital autumnal. This is a most useful sort, which accommodates itself well to circumstances—shuts up its petals at night, tightens its point in hot weather, and forms a beautiful buttonhole in the autumn, or when not thinned for show purposes.

François Michelin (Levet, 1871), of peculiar and very characteristic growth, with green, slender, yet fairly stiff stems, and thin poor foliage. This is the H.P. Rose *par excellence* whose performance is better than its promise. It seems incredible that those little buds on its spindly stems should open into what is one of the largest and finest show Roses we have; but they do. The petals look thin, and the growth seems so weak that an exhibitor, who did not know the Rose, would be slow to believe it would stand or hold its shape in a hot tent; but it does this too. But little affected by mildew or injured by rain, and coming generally well, but the centre, though almost always well covered, is sometimes not very regular. The outline is generally good, but the colour is not very lasting. Cannot be called a free bloomer, and is one of the very worst autumnals we have, a large proportion of the plants having no second crop. In propagating this Rose and others which are shy bloomers and bad autumnals care should be taken to bud from a flowering stem, for the young plant will probably not flower the first year if the bud has come from a "runaway" non-flowering autumnal shoot. Requires the Briar stock and rich generous treatment. We are

indebted to this Rose, I think, if we may judge from similarity of wood, &c., for one of the best introductions of late years, Mrs. John Laing.—W. R. RAILLEM.

(To be continued.)

HOLLYHOCK FUNGUS (PUCCINIA MALVACEARUM).

As a reader of the Journal I have been much interested in Mr. Alfred Bishop's valuable contributions. His remarks on "Fungus on Peaches," in last week's issue, page 505, have led me to ask, Can he recommend anything to destroy the Hollyhock fungus? The different species of parasitic fungi are now causing much alarm among horticulturists generally; few indeed are without their pet flowers, and as few, perhaps, are without some parasitic pest to blight their hopes, and often to destroy the work of years. From the simple Snowdrop of early spring, with which *Polyactis galanthina* plays such havoc when once introduced, to our summer queen the Rose, where orange fungus (*Coleosporium pingue*) wrestles hard for victory, on to our stately Hollyhocks, the glory of autumn, we have to fight with this destructive pest. It is in the latter flower that I am especially interested, and as I hold a valuable collection, a remedy would prove most acceptable, not only to me but to Hollyhock growers generally. Mr. Bishop is the first person I know who has been able to eradicate a parasitic fungus, and I hope he will throw a little more light on the subject, or perhaps our valuable critic, Mr. Tonks, would give us a wrinkle or two.

Mr. Bishop's remark at page 506, "I was now convinced the enemy was a fungus of some description, and treated the trees accordingly," leads one to think that he can eradicate my fungus. I hope, therefore, he will not take it amiss in my asking the name of his mildew composition, and whether he thinks it will destroy the Hollyhock fungus as effectually as that on his Peaches; if so Hollyhock growers may brighten up a bit, and we shall soon see the plant established in all its beauty. Will someone kindly tell us the origin and development of fungi, and also how they can be successfully eradicated?—G. STEEL.

THE SOURCES OF THE NITROGEN OF VEGETATION.

(Continued from page 406.)

It is not yet conclusively proved that the whole of the nitrogen of leguminous plants comes from the subsoil; it is equally not proved that it comes from the air; though in the case of crops belonging to other natural orders it may be affirmed that atmospheric nitrogen is not the source. May it be that the development of organisms capable of bringing free nitrogen into combination within the soil is favoured by leguminous growth and crop-residue, as there can be little doubt is the case with the organisms which produce nitrification? Frank has shown that on the roots of certain trees, especially the Cupuliferae, but also on Willows and some Coniferae, is a fungus-mantle which is believed to be in true symbiosis with the higher plant; and it may well be supposed that the fungus partly assists the tree by bringing the organic nitrogen of the soil into a form in which it becomes available to the chlorophyllaceous plant; much in the same way as has been observed by Gilbert in the case of fairy-rings, where the fungus, so to speak, prepares the nitrogenous nutriment for the grass. That the tubercles that are nearly always present on the roots of leguminous plants are in some way connected with the assimilation of nitrogen by the plants is an hypothesis that is gaining ground. Much study has of late years been devoted to the morphology and functions of these tubercles by, amongst others, Tschirch, Brunchorst, Frank, Van Tieghem, Lundström, and Marshall Ward; and still more recently by Bréal, Beyerinck, and Prazmowski. It seems almost certain that these tubercles contain micro-organisms, which are the proximate cause of the excrescences, and these may live in symbiosis with the legumes, and prepare their nitrogenous food possibly from free nitrogen. The tubercles are richer in nitrogen than the roots themselves, and some observers look upon them as being merely reservoirs of nitrogenous nutriment, not as manufacturing factories. Beyerinck (*Botan. Zeitung*, 1888) has obtained and cultivated an organism which he calls *Bacillus radicolica*, from these tubercles, and studied some of its reactions. It seems very probable that further study of these tubercles of the Leguminosae may put us on the right track for solving the mysterious nutrition of this order of plants.

In a postscript to the memoir the authors state that they have started some experiments with leguminous plants much on the same lines as those of Hellriegel and Wilfarth. The results of these experiments will be looked forward to with very great interest.

This memoir is a most welcome and solid contribution to a most important problem. It is quite obvious that the last word on the subject has not been said, and probably very much more work must be done before it is. The authors, from their own labours and thought on the subject, continued through so many years, are well able to criticise the work of others, and this they have here done, as far as most of the important papers published up to date are concerned, in an able and frank manner. If leguminous plants are able to avail themselves of the free nitrogen of the air, or if soils are able, through the agency of microbes or in other ways, to fix free nitrogen, the exact conditions necessary for the accomplishment of these ends is not yet known. The conditions of risk and exposure to accidental sources of nitrogen-gain in small experiments in the open air are very great, and experiments made under such conditions require very careful verification. Also the methods of

nitrogen determination used should be subjected to rigorous investigation and control, as also the methods of taking the samples used in analysis, which in the case of a complicated body like a soil presents great difficulty in obtaining a perfectly homogeneous mixture. The exact limits of experimental error in the various determinations want investigation. The subject, from its important practical bearings, is worthy the attention of a scientific commission who could give undistracted attention to it.

ROCK ROSES.

MANY species and varieties of the large genus *Helianthemum* possess sufficient attractions to render them worthy of more attention than they generally receive for planting in a variety of positions in the garden. The fugaciousness of their flowers is their chief failing, and doubtless that to a great extent prevents their being more appreciated; but although the flowers are of short duration individually, they are produced in abundance, and the colours are bright and varied. Most of the species are dwarf, erect, or trailing shrubs, and require a somewhat sandy or light soil. They succeed well on an ordinary rockery in nooks where more delicate plants would not thrive. They may also be planted in the mixed border or on banks, or in fact in any position where the soil is not too heavy. The popular name Rock Roses has been bestowed upon them because, owing to their five petals and numerous stamens, they bear some resemblance to the single wild Roses.

The best of the varieties and species are the following:—*H. vulgare venustum*, flowers small, of a peculiar bright crimson-scarlet colour, stamens yellow; very effective in dense masses. *H. v. macranthum*, flowers white with a yellowish tinge, very abundant. *H. v. serpyllifolium*, leaves small, bright green and smooth, flowers pale yellow. *H. v. roseum*, a compact little plant with numerous pretty rose-coloured flowers. *H. v. sulphureum*, flowers most profusely produced of a fine pale sulphur colour. *H. v. Lucy*, leaves dark green; flowers semi-double, purplish pink. *H. libanotis*, long linear dark green leaves, flowers small, yellow; a very distinct and old species. *H. rugosum*, a small trailing shrub, flowers bright yellow with a dark maroon centre; attractive and pretty. *H. polifolium*, downy leaves, white flowers, and yellow stamens, very pretty; this is a British species. There are, in addition to those enumerated, several very good double forms of *H. vulgare* that are bright and rather more durable than the single varieties.—C.

BULLFINCHES.

I HAVE been much interested by the correspondence on bullfinches, but I certainly cannot agree with Miss Ormerod's theory concerning the insects in buds. If every bud which these destructive birds pick out contained an insect we should have no fruit in this garden, for they simply begin at the top of the bush and take every bud out to the bottom; therefore if each bud contained an insect the birds may as well have them as leave them, for in either case we should have no fruit.

Have any of your correspondents observed any increase in the numbers of this beautiful bird? We have seen more in this garden this season than for many years past. They began on our Currant bushes with a vengeance as soon as the leaf was off, consequently we were obliged to apply our winter dressing much earlier than usual, which has proved effectual without exception "against all kinds of birds." It consists of soot, lime, Gishurst compound, and softsoap mixed with warm water, strained through a fine sieve, and applied to every part of the trees with a syringe. It sticks well to the trees, and since its application I have not seen where a single bud has been picked out. We are in the midst of birds of every kind. On the north side of the kitchen garden is a thickly wooded park and shrubberies literally swarming with birds. On the east we are sheltered by a town, just the home for the house sparrow, so it will be readily understood how we are situated. But I am a friend of birds, and can say truthfully that I have not allowed a single bird to be destroyed in these gardens this year, and the few fruits they have eaten have not been missed. I must confess they try my patience to the uttermost just as the Pears begin to ripen, for then they spoil many of the finest fruits, and it is impossible to protect all the trees from the daring sparrow and the impertinent little tomtit.—T. A. C.

ASCLEPIAS CURASSAVICA.

THIS species is one of the most attractive of the peculiar and interesting genus *Asclepias*, and its bright flowers very pleasantly enliven the appearance of a stove or intermediate house at the present time. As the cultivation of the plant is by no means difficult and the flowers are produced freely, it is not surprising that it should have early received the attention of cultivators; but even now, although introduced in 1818, it is not nearly so generally grown as it deserves. This is a South American species, and it bears numerous umbels of flowers the petals of which are reflexed and deep orange in colour, while the small cup-like appendages that form the staminal corona are bright yellow. The contrast is a very pleasing one, and the brightness of the colours is relieved by the dark green simple leaves that clothe the stems. There is also a white-flowered variety that is well adapted for a companion to the ordinary form.

In the treatment of these plants no especial skill is requisite, and few plants, considering the little attention they demand, produce more gratifying results. Propagation may be effected by cuttings, seeds, or

division of the plants, but the former method of increase is the most satisfactory. Cuttings should be prepared in the usual way early in spring and inserted in light sandy soil, the pots being placed in an ordinary propagating frame. When the cuttings are well rooted they should be carefully turned out of their pots and separated, injuring the young tender roots as little as possible. They may then be placed in 60-sized pots, employing a compost of loam, well-decayed manure, peat or leaf soil, and sand. As they fill the pots with roots shift the plants into larger pots and place them in the stove, supplying water freely. Flowers will be produced the first season, and a stock of these small plants is always useful for decorative purposes. As the plants go out of flower late in autumn remove them to a cool position, partially withholding water during the winter. In March turn the plants out of their old pots and remove some of the soil from their roots, repotting in the compost previously recommended. To obtain a succession pot batches of plants in March, April, and May, and by this means a supply of flowering plants can be maintained from June till October.—L.

NORTH AMERICAN SHRUBS.

(Continued from page 492.)

THE Choke Cherry, *Cerasus virginica*, with its panicles of white flowers, is one of the prettiest of our May flowering shrubs; its odour is rather agreeable, and its sour, red berries are eagerly eaten by the birds, and a single bush by a quiet roadside will frequently contain a dozen species of birds in a late August afternoon. A smaller shrub, called Choke Berry, *Pyrus arbutifolia*, has remarkably pretty clusters of white flowers with dark red anthers and very glossy leaves, and is usually found growing on the borders of open woods or moist roadsides.

Not a hedge, or sloping rocky hillside, or neglected field in all New England, but one can find, in June or July, the rosy pink buds and blossoms of one or more species of the single wild Rose. *Rosa lucida*, with few scattered prickles; *Rosa nitida*, with dense red ones; *Rosa blanda*, with few prickles, but no shine in the leaves; *Rosa carolina*, with recurved prickles; and the Sweet Briar, with its smaller and fragrant leaves, and its great, stout, thorny branches. Blackberry Vines are not generally looked upon as ornamental, but they are a pretty sight when growing by the roadside, overtopping all other shrubby growths with their masses of bee-haunted, snowy flowers, with occasionally the golden-yellow, black-spotted Turner's butterfly hovering above them.

The *Crataegus*, or Hawthorn family, blooms the latter part of May in New England. The flowers of all species are very fragrant, and the shrubs, which are almost trees, are all armed with sharp thorns, and the leaves are lobed and crenate. The calyx remains on the scarlet fruit, which turns brown after frost, but hangs on until eaten off by birds in the late winter. The flowers of *C. Crus-galli* are larger than *C. punctata* or *C. coccinea*, and none of these are as pleasantly fragrant as *C. oxycantha*, or the English Hawthorn, with its already naturalised in many parts of New England, and whose clusters of flowers wreath the thorny branches so densely as to hide the small shining leaves which are about half grown at the time of flowering. The petals of all these take a pinkish tint before they turn an ochreous brown and fall off.

The climbing shrubs that are called Honeysuckles are somewhat rare in New England, with the exception of *Lonicera parviflora*, which is commonly known as Woodbine. Its whorls of yellow, red tinged, tubelike flowers are succeeded by orange-scarlet, soft, pulpy berries. It is a slow grower, but is hardy, never troubled with insects, and blossoms profusely in May and June. One of our few yellow-flowering shrubs is the *Diervilla*, or Yellow Honeysuckle. It is common in thickets and bush lands, and is well known by its opposite, deeply notched leaves and its clusters of faint-scented yellow flowers, which appear in June.

One of the handsomest of all our native shrubs is the Elder, *Sambucus canadensis*. Its glossy pinnate leaves and great flat cymes of creamy white fragrant flowers make it a very desirable addition to our list of shrubs that should be cultivated. A basket of Elder flowers and Roses is "a thing of beauty" that will be "a joy for ever" in the memory. The *Viburnum* family supplies us with many flowering shrubs, of which the best known is the Cranberry Tree, *V. Opulus*, whose white radiate cymes are succeeded by large scarlet berries, which resemble the Cranberry in appearance and taste, and are used as a substitute for it in many places. *V. Lentago*, or Sweet Viburnum, has spreading cymes of white flowers in June, and black sweet berries in late autumn. The berries of *V. nudum* are bright blue covered with a bloom, and are dainty bites for the birds preparing to migrate.

A shrub that always attracts attention in the swamps is the *Cephalanthus occidentalis*, or Button Bush. It is easily found by its round ball-like heads of white flowers, which remind one of the seed-balls of the Buttonwood or Sycamore. It is in bloom in August. The greater number of our shrubs flower in May and June, and this is particularly true of the Heath family, the colours of whose flowers are in tones of white or red, no yellow or any suggestion of blue. The Huckleberries and Blueberries are so pretty, with their clusters of pearly white or pink bells in the open woods or the rocky pastures, but they will not bear transplanting.

The beautiful Laurel, *Kalmia latifolia*, is the queen of New England shrubs, with its magnificent cymes of flowers in all shades from white to deep rose. Its glossy evergreen leaves are said to be poisonous to cattle. Here and there in low woods, and especially in burnt-over lands, we step over the little bush called Sheep Laurel, *Kalmia angustifolia*. Its small clusters of purplish-pink flowers would be thought pretty if it did not suffer by comparison with its lovely relative.

The trailing shrub which grows dearer each Christmas-tide is the *Arctostaphylos Uva-ursi*, or Bear Berry. Its long branches so thickly set with the small, ovate, glossy evergreen leaves, varying in colour from the dark green nearest the roots to the shining red ones on the tips of the youngest branches, make it our favourite evergreen. It retains its colour and beauty through the winter in the house, but its few scarlet tasteless berries drop off almost as soon as it is gathered. Its dainty pinkish bells hang from the under side of the branches in May and June. Helen Hunt Jackson's description of the Kinnikinnick Vine, of Colorado, applies equally well to its near relative, the Bear Berry.

Look through the trees and catch a glimpse of that great rosy cloud, draw nearer, and the dearest flower to New England is before you, *Azalea nudiflora*, or Swamp Apple, or Honeysuckle, as it is variously called. Break off the great pink balls of fragrance and loveliness, and put with them the feathery young green shoots of the Hemlock, and as you look at them lovingly, thank God for the beauty of bleak New England. *Rhodora canadensis*, with its naked, smooth, brown twigs and the purplish-pink flowers clustered on their extremities, is met with by the roadsides the last of May. It is always noticed by the entire absence of leaves, although a late season sometimes shows a tip of pale green among the flowers.

Seldom found in the interior but abundant on the sea coast, filling the air with its spicy fragrance, grows the *Clethra alnifolia*, or Sweet Pepper Bush. Its long, white, waxy spikes stand upright; in some localities it is found growing 10 feet high. Its usual height is 3 to 5 feet. It grows abundantly about some inland ponds, as well as on the edges of salt marshes, and in both places seemingly disputing the right of way with the graceful climbing Clematis, or Virgin's Bower, which last appears to conquer, as it waves triumphantly in the autumn sunshine, its feathery, plume-like seed vessels for banners of victory, mingled with the blood-red leaves of the tall Blackberry.

No one notices the Black Alder, *Prinos verticillatus*, in summer, but when the leaves have all fallen from the dense bush-growth in the moist low lands, then the eye is drawn thither as if by magic. A north-west wind, a whirl of the leaves, and lo! the swamp is aflame; the scarlet berries gleam in the sunshine like g'obes of fire. Sassafras is well known by its aromatic fragrance, which is in root and bark as well as in its curiously lobed leaves. *Benzoin odoriferum*, or Spice Bush, is known by its golden-yellow flowers, which appear before the leaves in May, and are followed by ovoid scarlet berries in autumn. Frost comes, and along the roadsides the fuzzy involucre of the Hazelnut expands, disclosing the sweet well-flavoured nut that the farmer's boy, driving the cows at sunrise to the meadow pasture where the grass is still green, stops and fills his jacket pockets with, as he whistles merrily, as only a farmer boy can. The *Corylus americana* is our only nut-bearing shrub. Along the banks of streams in most parts of New England grows the *Alnus serrulata*, or Smooth Alder. Its clusters of dark brown fertile aments hang on all winter, and the yellow pollen of the sterile ones in early spring turns them with its Midas touch to gold when the air is still.

Many of us who in childhood have had our burns and bruises rubbed over with grandmother's Bayberry salve have an affection for the low-branched shrub, *Myrica cerifera*, with its pungent spicy odour, and its green ovoid berries covered in a waxy tallow, which we have gathered so many times in a sloping pasture lot on an old farm in Connecticut. We always find the dear old Sweet Fern, *Comptonia asplenifolia*, in the same locality, not half so readily noticed in the summer when its low growth is hidden by taller shrubs, but when the leaves have dropped in autumn, then the Sweet Fern dots the pastures with its long burnt sienna-coloured patches, making a vivid contrast to the red-capped Lichen at its roots, which is called by the little ones, "Robin Hood's merry men in green."

Indian summer comes, and the pale purple haze hangs between us and the hills. The leaves with no vestige of their gorgeous autumn tints remaining, lie in scattered heaps upon the ground. Only the Oak rattles his brown foliage in defiance, when the Witch Hazel, *Hamamelis*, sends out its pale blossoms, its long, narrow, twisted petals having an uncanny look against the background of the Hemlock. The woody capsules, with their two white seeds, seen like elfish grinning brownies daring you to pluck these last blossoms of the year. The yellowish sessile flowers remain on the greyish-brown branches all winter, and it is not so rare a thing to find the long petals twisted about each other still retaining their colour, but dry and papery, when in your woodland walk, on some May day that has walked backward into April you gather the first unfolding blossom of the *Dirca*.—FLORENCE I. W. BURNHAM (in *Vick's Magazine*).

Cucumber in winter, and now the days are so short keep the glass as clean as possible both inside and out. Do not apply strong liquid manure too freely, as it is the reverse of good treatment to stimulate them unduly at any time. The soil, however, applied to the roots should be rich and sweet. Be careful not to overcrop the plants, and do not allow the fruits to hang too long. They keep fresh several days after being cut if the "heels" are inserted in saucers of water in moderate heat. Remove superfluous fruits as they appear, and tie the growths as necessary. Red spider should be subdued by syringing the infested leaves with a weak solution of softsoap 2 ozs. to the gallon—a safe remedy, but care must be taken not to damage the leaves. If mildew appear, dust the affected parts with flowers of sulphur, and reduce the atmospheric moisture. Green or black aphides may be destroyed by dusting them with tobacco powder, or fumigation on two or three consecutive evenings moderately. An overdose may do irreparable injury.

Where early Cucumbers and Melons are obtained from frames or pits heated by fermenting materials, some fresh Oak or Beech leaves should be thrown together, with one-third of stable litter, and, if necessary, be moistened so as to induce fermentation. It should be turned when warmed through, alike to sweeten, to bring all into a genial state of warmth by turning the outside to the inside, and to induce thorough incorporation of the materials.

PEACHES AND NECTARINES.—*Earliest House*.—Cease syringing the trees when the blossoms show colour, maintaining, however, a moderate moisture in the house by damping the floors on bright mornings and in the early part of fine afternoons. The temperature may be maintained at 55° by day, 50° being sufficiently high for the night, and if the temperature fall to 45°, and in very sharp weather to 40°, it will be more an advantage than otherwise. Examine the inside borders, and give if necessary a thorough supply of water at a temperature slightly in advance of that of the house.

Second Early House.—The trees for affording fruit at the close of May or early in June must have their final dressing if one be necessary, be tied to the trellis if not already done, and the border inside well watered, as nothing tends so much to encourage the development of strong flowers as a good soaking of liquid manure not cold enough to chill the roots. The house should then be closed, employing no more fire heat than is necessary to exclude frost, damping the trees in the morning and early in the afternoon of bright days. Fire heat must be applied to raise the temperature to 50°, but not more, and above that air must be admitted freely. Protect the outside border with dry fern or litter, and if means are at command for throwing off heavy rains or snow it will be desirable to employ them.

Succession Houses.—Push forward pruning and dressing trees after loosening them from the trellis, cutting out any weak attenuated wood, and where crowded thin well, leaving space between the current bearing wood for training in that intended to displace it. Secure the branches at once to the trellis, leaving space in the ties for the swelling of the shoots—i.e., secure loosely. The surface soil should be removed down to the roots without disturbing them, and give fresh material—good tufty loam with an admixture of well decayed manure, about a fourth, and a twentieth of steamed bone meal, not covering the roots more than 2 or 3 inches deep. Carefully examine the inside borders, as dryness at the roots will cause the buds to fall later on.

Houses that are to be started early in next year should be kept cool. If the lights have been removed let them so remain until it becomes necessary to replace them for starting the trees. Complete the needful operations in cleaning, pruning, and dressing, also tying the trees to the trellis.

FIGS.—*Unheated Houses*.—Unloose the trees from the trellis or wall, have the branches tied together in convenient bundles, and cover them with a single thickness of mat and then some dry straw or fern a few inches thick, securing with tarred string, mulching the roots with some short rather littery material to a depth of not less than 6 inches; this insures safety to the roots, whilst the covering with straw or other material will not only insure the branches against frost, but tend to a more complete state of rest.

Unsatisfactory Trees.—These may be due to various causes. It is usually on account of the soil; there may be too much, or it may be too rich and loose. A dressing of lime an inch thick may be pointed in as deeply as the roots will permit without disturbing them much, and after resting a time and when in good order tread it firmly. If the trees make long-jointed wood the better plan is to lift them carefully and replant, making the soil more firm, using the lime all the same. If the borders are wide restrict their area, and if the soil be of a light nature an admixture of clay marl will improve the staple, tend to encourage shorter-jointed wood, and increase the size and quality of the fruit.

PINES.—Preparations must be made for producing ripe fruit during the months of May and June. Smooth-leaved Cayenne, Black Jamaica, and Charlotte Rothschild, which failed to show fruit during October and November, will not now throw up in time to ripen at the period in question; and attention must be directed to such as attain perfection in less time, such as the Queen, Enville, Providence, &c. Choose at once these plants which have an enlarged base, with a tendency to open at the centre, signs of the fruit being shortly visible, placing them in a light house or pit, affording brisk bottom heat of 85° to 90°, a top heat of 60° to 70° at night, 70° to 75° by day, and 10° more when the external conditions are favourable. A genial atmosphere should be maintained, but not produced by steam resulting from syringing the hot water pipes, as syringing the plants once or twice a week is ample, and

FRUIT FORCING.

CUCUMBERS.—The weather may not have necessitated sharp firing, but there has been an absence of sun, which generally results in a weak attenuated growth. Light is very important in the cultivation of the

then very lightly, on fine afternoons damping the house. See that the soil is in a proper condition as to moisture, using tepid water with a dash of guano or some fertiliser in it, applying it copiously when required, which will be about every ten days.

THE FLOWER GARDEN.

Herbaceous Plants.—When the ground is fairly dry, and the weather mild, advantage may well be taken of a favourable time to lift, divide, and replant many of the stronger growing hardy occupants of the mixed or herbaceous borders as may need it. All in time become either too large for the site, or else present a less healthy appearance, owing to having exhausted the stock of food contained in the soil. The first to become crowded and exhaust the soil are the Phloxes, Delphiniums, Spiræas, Campanulas, Potentillas, Hemerocallis, Asters (Michaelmas Daisies), Pyrethrums, notably *P. uliginosum*, Heleniums, Chrysanthemums, Helianthus (Sunflowers), and *Anemone japonica*. About every third year these pay well for lifting, dividing, and as many as are required replanted, either in their old stations, after some fresh soil and manure has been added, or, better still, in quite fresh quarters. When crowded and starved, the flowering season is frequently of short duration, especially if they have to pass through a hot dry summer; whereas, when freely divided and replanted in fresh rich soil, they are much less affected by drought, and in any case the quality of the flowers is superior. Plunging forks, and in some cases ordinary digging forks, are much the best for dividing strong clumps, and when replanting the divisions take good care to well bury and firmly fix the soil about the roots, without, however, unduly lowering the hearts of the plants. Less vigorous plants, and which are too numerous to name here, may well remain undisturbed for a much longer period, or say double the time of the strong growers, and these require to be more carefully handled.

Re-arranging Herbaceous Plants.—Not unfrequently old, and, it may be, somewhat neglected mixed borders, would be greatly improved by being re-arranged, and on the whole the present time is, weather permitting, as suitable as any for this important work. It is true they are more often taken in hand in the spring, but in most gardens there is usually much other work to be attended to, and besides this also greatly interferes with the display made by early-flowering bulbous plants. Old clumps of the latter are in many instances now rooting freely, and at this stage of growth may be lifted, divided, and replanted without detriment to their flowering either during the next or following spring. Supposing it is decided to completely re-model a border, the first proceeding should be to well scrape back the loose gravel on the walk near at hand (and such are very general), and on this set the clumps of plants and bulbs, according as these are carefully searched for and forked out of the ground. If the nights are somewhat frosty, or the weather unsettled, too great a length of border should not be broken up at one time, or not more than can be trenched and replanted in one day. In most cases double digging or bastard trenching only ought to be resorted to, abundance of half-decayed manure being mixed principally with the top spit. There is no necessity or wisdom in returning the plants to the borders in formal lines, the better plan being to plant them somewhat irregularly, due regard being paid to the respective heights of the species and varieties, care also being taken to well mix them so that the early flowering kinds may alternate with those much later in coming into flower. Nor is it advisable to plant rather thickly, there being a considerable number of half-hardy plants that room should be found for in herbaceous or mixed borders. All, whether bulbous or otherwise, to be correctly labelled, the simplest and best kind of label being made from 1 foot lengths of sound Hazel rods, these being pointed at one end, and faced and painted white at the other. Mulch with manure or leaf soil after the border is planted.

Manuring and Mulching Borders.—The least that can be done to an herbaceous border is to thoroughly clean and mulch it at this time of year. All tender plants, whether dead or not, ought to be removed, and the dead tops of the hardy occupants trimmed off, and these, with any weeds there, may be consigned to the rubbish heap for burning. The surface of the border may then be very lightly and carefully forked up, the greatest care being necessary where many bulbs are grown, after which a liberal dressing of partially decayed manure, with loam added if it can be spared, and also charred rubbish, or the contents of a "smother" generally should be applied. Old Mushroom-bed manure is good for the purpose, and so also is a heap of leaves and manure that may previously have done duty as a hotbed or Vegetable Marrow heap. This mulching will answer the double purpose of enriching the border, and also to a certain extent as a protector of the roots from severe frosts. Bulbous-rooted plants, if planted sufficiently deep, are, as a rule, quite hardy, but if within 2 inches of the surface they may well be protected with a mound of either ashes, cocoa-nut fibre refuse, or leaf soil.

A Selection of Hardy Flowering Plants.—There is an almost unlimited number of species and varieties of serviceable and beautiful plants suitable for filling mixed borders, and which may be purchased and planted at the present time, the only exception being where the pieces are too tiny to be trusted to the tender mercies of slugs and other enemies, including a careless gardener's feet. The following, arranged much in their order of flowering, would be found very satisfactory:—*Leucojum vernum*, Snowdrops, Crocuses, *Chionodoxa Lucilæ*, Narcissi and Daffodils in great variety, German Irises, *Anemones appennina*, *syvestris* and *fulgens*, *Cheiranthus alpina*, *Polemonium Richardsi*, *Ibericus gibraltarica*, Alpine Auriculas, *Primulas Sieboldi* and *vulgaris* in variety, *Dodecatheon Jeffreyanum* and *media*, *Gentiana acaulis*,

Aquilegia, hybrids of *cœrulea*, *californica*, and *glandulosa*, *Anthericum liliago* and *liliastrum*, *Dielytra spectabilis*, *Campanulas glomerata* and *dahurica*, double Pyrethrums, *Centaureas montana* and *alba*, *Erigeron aurantiacus*, *Hemerocallis flava*, *Lupinus nootakaensis* and *polyphyllus*, *Ornithogalum umbellatum*, *Papaver bracteatum*, Solomon's Seal, *Trollius asiaticus*, *Verbascum phœniceum*, *Tradescantias virginica* and *alba*, double Potentillas *Gloire de Nancy* and Dr. André, double white Rocket, *Geraniums armenum* and *ibericum*, *Erigeron speciosus* and *macranthus*, *Dianthus barbatus magnificus*, hybrid Delphiniums, including *Belladonna* and *formosum*, *Asphodelus luteus* and *ramosus*, *Pæonies* in variety, Spanish and English Irises, *Veronica spicata*, *Spiræa aruncus*, *filipendula plena* and *venusta*, *Pentstemon barbatus*, *Oenothera speciosa*, *Galega officinalis*.

PLANT HOUSES.

Poinsettias.—As the bracts of these fail the plants needed for stock should be given careful treatment afterwards. Do not transfer them at once from a warm to a cold structure, but remove them gradually, and with the same care diminish the supply of water until it will be safe to keep them perfectly dry and cool. Plants that are doing duty in the conservatory will need no more water than will keep their foliage fresh; these when the bracts fail will do very well in cool quarters.

Euphorbia jacquiniæflora.—Plants that have flowered in the stove need also the same careful treatment. They are liable to suffer if kept too wet or suddenly kept too dry. These after flowering should not be placed in too low a temperature; after they have been gradually hardened and can be kept dry, they will be perfectly safe in a temperature of 50°. However beautiful these may be while in flower in the stove, they are much more useful in the conservatory where the temperature is not allowed to fall much below 50°, they also last double the length of time. Where nearly all flowering plants have to be employed in this structure there is a tendency to stiffness at this season of the year unless such light graceful plants as the one under notice are grown in quantity and utilised for standing well above plants of a dwarf compact nature. By the aid of Poinsettias, Euphorbias, late Calanthes, and plenty of *Centropogon Lucyanus* formal arrangements need not exist. Some care is necessary in removing the latter from heated to cooler structures, or else its foliage turns yellow and quickly disfigures its appearance. Plants that have produced in the stove their terminal truss may be bent round four or five small stakes, when they will soon break into growth and flower again.

Justicia flaricoma.—Plants that may have flowered should not be thrown away; if they are retained they will flower again, and in a short time will produce better plumes than they did at first. In all gardens where effective arrangements are needed during the first four months of the year this plant should be grown in quantity on a single stem in 5-inch pots.

Linum trigynum.—Those having flowered should be cut well back. It is not necessary to retain many plants for stock. Those that are retained, if they have been infested with red spider, should be thoroughly cleaned. The best means is to remove all the foliage and sponge their stems with a strong solution of an insecticide. Plumbagos may also be cut back. The foliage should not be removed from this plant. Its greatest enemy is thrip, which can readily be destroyed by dipping in a solution of tobacco water.

Coleus and Tradescantias.—Both these are useful in small pots for various purposes of decoration. The latter will root quickly and freely enough in any heated structure, while the former should not be in a lower temperature than 65°. They strike freely enough inserted in the pots from which they are to be used if stood on a shelf over a hot water pipe. They should be kept moderately moist.

Selaginella Kraussiana.—This is most useful in from 3 to 5-inch pots for a variety of purposes. Fill pots with light soil in which plenty of fine leaf soil has been incorporated well above the rim, and prick thickly into them growing ends of plants that have been reserved for this purpose. If placed in a warm moist house they will quickly root and cover the surface. It is a good plan to make up a few pots according to the demand, at intervals of a fortnight.

Polystichum proliferum.—A useful Fern in any size pots up to those 5 or 6 inches in diameter. We find it most useful in 4-inch pots. Plants placed in these in autumn and have been kept cool, may be introduced into a temperature of 50° to 55°. Remove the old foliage and plant a little *Selaginella* round the crown, and they will soon push up new fronds, and in a few weeks be ready for any form of decoration. Some in small pots to replace these may be placed into large, and *Selaginella* dibbled in at the same time, not too thickly, or it outgrows the plant when they are first potted. These will do capitally in a Peach house or vinery that has been started, in fact in almost any position until they begin to grow.

Adiantum cuneatum.—Where all the fronds have been gathered that are of any service, the old plants may be cut over, and if slugs have infested them they should be well dusted with soot. Place these plants in a temperature of 40° for a few weeks to rest. Be careful not to overwater plants that have just started into growth; for these a temperature of 60° will be ample, while those with abundance of fully developed fronds should have a temperature 5° lower. Any plants that display signs of growing should have fronds that are ready for cutting removed to give the young ones a chance, and should be encouraged to grow. Fern fronds will be less plentiful during the next two months than what they are now, unless ample provision has been made to maintain a supply.

THE BEE-KEEPER

NOTES ON BEES.

GLASS SECTIONS.

"A SUSSEX AMATEUR" asks for information regarding the using of tin for holding glass sections together. Many years ago I had a fancy for making tin and zinc corner pieces for holding squares of glass together. These were used for the protection of flowers, for striking cuttings under, and for the protection of tender seeds and plants in spring or autumn, as well as for holding small supers of glass together when on the hive. These were not for myself alone, I occasionally sold them to others. The advantages were that when not in use they were easily taken to pieces and stored. The disadvantage was that they only held together when there was no draw upon the glass. I think then that tin fasteners or corners are ambiguous terms, and cannot be binding unless they are of a special make or form. If these are new then the patentee must be protected, but if not any person may make without the fear of prosecution.

FEEDERS.

These are numerous and have been explained often, so that it might appear nothing more need be added nor another wanted. At page 453 I mentioned two superior and useful feeders; the one I am about to mention now is on the same principle, but is more serviceable for work at the Heather. It sometimes happens that bees at the moors for want of fine weather become decimated, so that when fine weather comes there are not bees enough to gather much honey, whereas by timely feeding the bees would have been all alive and much honey secured. Top feeders are of no use at the Heather. A good bottom feeder, and for all purposes is a tin, square in shape, and large enough to hold from 2 to 4 lbs. of sugar after it is dissolved. Any amateur who can handle a soldering bolt can make them easily enough, and at an outlay of 3d. or 4d. each. A tin scoop about 2 inches broad and not more than three-eighths of an inch deep, which may be left permanently in the hive. This should be covered at the outer end to the extent of the size of the fountain, and a hole pierced in it sufficient to admit the neck of the fountain, which is a brass screw, such as is used for oil cans about an inch in diameter. A hole about an eighth of an inch in diameter is drilled right in the centre, and counter sunk on the upper side, or it may be flat; a screw nail let into this acts as a valve, and a bend or a small nut on the other prevents it falling out. It need not be more than 1 inch long. This is the part I have never before described, the valve never gets out of order, and by using so large a screw it is easily filled or emptied. Of course a pane of glass improves it but costs more. Its usefulness consists in addition to being an all-round good feeder is an indispensable one for feeding bees when at the Heather, and bee-keepers studying their own interests should include one for every hive in their winter's work.

USEFUL SUBSTANCES.

Petroleum is useful in many ways about the apiary, removing paint and grease, and for lubricating rusty hinges.

Turpentine is fatal to moths, and as it volatilises readily, hives and supers containing comb should have some of it applied. It is not the hives and combs alone that suffer, but every woollen or fur garment is very soon rendered useless by their depredations if allowed to increase unchecked, so that no pains should be spared to exterminate the pests.

Carbolic acid should be frequently used on all bee appliances, and good follows if combs to be used in stock hives get a slight sprinkling and kept close for some time after.

OIL CLOTHS.

Cotton cloth steeped in boiled linseed oil makes a pliable and light but effective covering for bees at the Heather, as well as for surplus stocks at home. Sew several plies of cloth at each corner, then put in a brass ring, steep in oil, then drip, and stretch out to dry. A few subsequent dressings with a cloth or brush add

to its closeness. As these when new are sticky they should be prepared long before wanted. Do not use any paint, nothing but oil.

FOUNDATION.

Procure this and all supers and frames fitted with it during winter. A word of caution as to its use. Many bee-keepers fill sections and supers with it, which gives a greater quantity of honey, but of inferior quality. Those who go in for quantity use full sheets, and have to be contented with a lesser price, while those who go in for quality can easily dispose of it, in the face of a glutted market too, and at a higher figure. The latter are those who are really creating a desire for honey amongst the million, which will result in more profit. The former may be causing more sensation, but are shutting the door against future profits.

DRIFT HONEY.

Although black combs are not seen, when drained from them is often sickening, and as the people become learned to the right flavour will reject such. A coloured super gives quite a good sample of drift honey, but if bees were managed as they should be it would be the exception and not the rule, as it still is in many quarters.

Honey drift from long-bred-in combs should not be offered for sale as a first-class article, but as an inferior sample, and labelled as such. Some people contend that storing honey in bred-in combs does not affect the flavour, but it does so, to a very great extent too. Honey soon becomes spoiled if stored in a damp place or exposed to the air, or to a great heat to prevent granulation. I drew the attention of one bee-keeper to this lately who stored fine honey in a damp milk house, which has spoiled it greatly. On my suggestion he has put up a wooden erection where it will be free from damp or atmospheric influence.—A. LANARKSHIRE BEE-KEEPER.

GLASS SECTIONS—PATENT RIGHTS.

WELL done Mr. Editor for (on page 518) putting temptation out of our way. We have been longing to see the great discovery of "A Hallamshire Bee-keeper." From the letter that appeared from him some months ago, many were led to believe they were going to be shown the way how to make these glass sections themselves at the trifling cost of 10s. per 1000. Families might thus employ themselves during winter evenings, and the tools were to cost a trifle; but alas! we are disappointed. Why didn't "A Hallamshire Bee-keeper" tell us plainly at first of his intentions? But for the Editor we might have been led into a trap. Your correspondent has a right to enjoy the fruit of his labour and to patent what he can, and I hope all the friends of the bee wish him success. For some months past I have been trying to think out some plan for making glass sections, and have at last succeeded. I have been at a great disadvantage, having never seen a glass section. I have made two patterns, they are put together very soon without tin and at very little cost. I will try them next summer and if they turn out as I expect, I want them for exhibition purposes, and will then let the readers of this Journal know more about them.—A. HOWDENSHERE BEE-KEEPER.

* * All correspondence should be directed either to "THE EDITOR" or to "THE PUBLISHER." Letters addressed to Dr. Hogg or members of the staff often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

To Inquirers and Correspondents.—In consequence of the necessity of making up the pages of the present issue of this Journal several days in advance in view of Christmastide, answers to some letters must be deferred to a future issue.

Stocks (Moss Rose).—If you send us a stamped directed envelope the information you require will be supplied.

Celery Decaying (J. H.).—If the whole of your Celery is like the sample sent it is next to worthless. It was impossible to have anticipated its condition. The leaflets as they push from the flower stem into wet and possibly heavy soil are almost certain to perish, as in the example. There is no means of checking the evil, and the only

certain method of prevention is to prevent the plants "bolting" by care in preparation and after management. The one sent appears to have been drawn too much before it was planted. We have not one bolted plant out of a thousand.

Mealy Bug on Vines (*A. Young Gardener*).—Whether you add tan to the mixture or not for "filling up the cracks" in the Vines you will not eradicate the pest by dressing the rods alone. Remove all loose and scaly bark, then apply the softsoap solution with a wine-glassful of petroleum added, brushing in it vigorously at a temperature of 130°; indeed, give the rods a thorough good scrubbing, and if the work is done well not an insect will remain alive. But that is only a small part of what needs to be done. Every part of the house must be cleansed, roof, wires, walls, stages, especially the part usually unseen, for the insects lurk in all sorts of unlikely places—in bits of matting, the under sides of stages, fissures in walls or woodwork, in the soil near hot water pipes, among the drainage in flower pots—in fact they may be the most numerous where you least expect to find them. If there are plants in the house every one must be cleansed, and if there is an inside Vine border the surface must be removed and fresh soil added; in short everything you can think of should be done for destroying the insidious enemy. Then in spring a watchful eye must be kept for insects that may have escaped your vigilance, promptly destroying every one you see, or the Vines will soon be infested again.

Winter Heaths (*C. S.*).—Such Heaths as *Erica hyemalis*, *E. autumnalis*, and others that have flowered early and are past their best for decoration, should be cut close back if they are intended to be utilised for the same purpose another autumn. If they have been in structures where heat has been maintained, they should not be placed direct into the cold greenhouse or they will be seriously checked. They should be gradually hardened to greenhouse treatment, so that they will start into growth slowly but naturally. Plants that have long been in rooms for decoration are useless for growing another year. All plants employed for such purposes are better conveyed to the rubbish heap as soon as they are removed, for they are not worth the trouble necessary to restore them to health. Young plants in small pots that are intended for flowering another year must be kept in a light position and as cool as possible, so that they will not be excited into growth. Any plants that did not show flowers and are dwarf and bushy should be subjected to the same treatment. These plants should be watered carefully, taking care never to allow them to suffer by an insufficient supply.

Gleichenia Culture (*W. W.*).—They require to be grown in rough peat, torn in pieces with the hand and the finer particles rejected. Brown fibrous peat is the most suitable. Good drainage is necessary, and deep pans will answer quite as well as pots, they not being deep-rooting plants. The plants should be potted when they begin to grow, or early in March, and the soil removed without injuring the roots. To the soil, before potting, add about a sixth of charcoal broken small, and a similar quantity of crystal sand. Work the soil in carefully amongst the roots, keeping the rhizomes well up, and potting moderately firm. Water thoroughly, so as to settle the soil about them, and do not water again until it is necessary, but before the plants are distressed by want of it, then giving a thorough supply. They are best in a light position, with just sufficient shade in very bright weather to prevent scorching, and should have a rather free amount of air, as they do not flourish in the close moist atmosphere of ordinary ferneries. A moderate amount of moisture only is necessary, and water should be sprinkled on the fronds. They require a temperature of 45° to 50° in winter, and 55° to 65° in spring by artificial means, and 10° to 15° rise from sun heat. The summer temperature will range 60° to 65° at night, and proportionately higher in the daytime. The chief things are an open free soil, free ventilation, and not too much water either at the roots or in the atmosphere.

The Common Holly, *Ilex aquifolium* (*X. M.*).—This is a native of the woods and forests of Britain; and its numerous varieties of gold and silver-blotched, entire, notched, serrated, ciliated, bristly, broad, narrow, and thick-leaved, and yellow-berried, are beautiful ornamental trees in parks and shrubberies; and especially in winter, when covered with a profusion of bright scarlet berries, a large Holly tree is perhaps the queen of the woodland. For a fence there is no better tree than the Holly. It never suffers from the severest winter; it is always green, strong, and impenetrable, and it is easily kept in order. The leaves are mucous, bitter, and astringent, with an austere taste; they were formerly used as a diaphoretic, and, in infusion, were considered beneficial in catarrh, pleurisy, small-pox, and gout. A few years ago they were highly extolled in France as a cure for intermittents, and were considered equal to Peruvian bark, their febrifuge virtues being said to depend on a bitter principle called ilicin. The berries are powerfully purgative, and also an emetic and diuretic; ten or twelve will act on the bowels. The expressed juice has been used in jaundice. From the bark the substance called bird-lime is obtained, by boiling it for some hours in water, till the green part separates from the white; then laying it in a cool cellar for some days; afterwards pounding it till it becomes a tough paste, washing it frequently till it becomes clear, and then placing it in an earthen vessel to ferment or become fine, when it will be fit for use. The wood is hard, with a fine grain, and a colour almost as white as ivory, except at the heart of old trees, where it is brown; it is capable of receiving a high polish, and is readily stained of any colour, but the most common is black in imitation of ebony. It is much used for inlaying and cabinet work, and it forms a considerable ingredient in Tonbridge-ware; it also forms handles to knives, and has even been used for wood engraving.

Present Treatment of Cyclamens (*R. M. S.*).—Plants that have been kept cool up to the present time, and are wanted in flower, should be introduced to some structure where the temperature can be maintained at 50° to 55°. They should be arranged as near to the glass as possible, or the flower stems will become tall and weakly. Free ventilation should be given on all favourable occasions. Weak stimulants may be applied to these as well as later batches that are to remain under cool treatment for some time longer. Young stock in small pots should be kept slowly growing, and if they have been subjected to cool treatment they will do this in a night temperature of 45°. They must be near to the glass to keep their foliage dwarf and sturdy. Take care that plants in small pots do not suffer by the want of water, and on the other hand the soil must not be saturated. Watch for aphides, and if they appear on the under side of the foliage destroy them at once, either by fumigating with tobacco or dipping them in a solution of tobacco water. For a stock of flowering plants another year seed should be sown at once. A pot or pan may be prepared, according to the quantity of seeds to be sown, by draining it thoroughly, and then nearly filling it with light soil that has been passed through a fine sieve; a suitable compost is equal parts of loam and leaf soil with a liberal addition of sand. Sow the seed evenly upon the surface and just covered with fine leaf soil. If the soil is in a proper state of moisture no water will be needed for at least a week after sowing, if the pan is plunged in a heated structure and covered with a square of glass. Care must be taken to avoid the soil becoming dry after the seed is sown. After the seedlings appear above the soil they should be gradually exposed to the light and grown close to the glass.

Names of Fruits.—The names and addresses of senders of fruit to be named must in all cases be enclosed with the specimens, whether letters referring to the fruit are sent by post or not. The names are not necessarily required for publication, initials sufficing for that. Only six specimens can be named at once, and any beyond that number cannot be preserved. (*H. P. W.*).—The Apple is Winter Majetin.

CHRISTMAS CATTLE.

RIGHT royally has Her Majesty the Queen done credit to her position as a model farmer and as President for the year of the Royal Agricultural Society of England in the recent exhibitions of Christmas cattle at Birmingham and at Smithfield. At Birmingham there were eight animals entered for competition from the royal farms, with which Her Majesty won four first prizes, three second prizes, two high commendations, a reserve, the two breed championships for Herefords and Shorthorns, as well as the championships for the whole Show. At Smithfield even more remarkable results were achieved. Thirteen animals were entered, with which Her Majesty gained six first, two second, and three third prizes, the Shorthorn breed cup, the best ox or steer cup, and the champion prize for the best beast in the Show. The royal champion ox is a Shorthorn, about forty-three months old, and its weight is 23 cwt. 17 lbs. Seen alone it would doubtless impress one more than it did as we saw it at Islington. It is undoubtedly a grand animal of very noble proportions, but its age was against it, and the Judges were a long while in coming to a decision both at Birmingham and Smithfield, its rival at both Shows being Mr. Clement Stephenson's polled Aberdeen Angus heifer, weighing under 14 cwt., but nevertheless a beast of superb quality, which no doubt told with the Judges much more than mere size would do. Anyhow, it is one more triumph for the Shorthorns, or rather a double victory. Even our favourite Devons were beaten by the royal champion in the contest for the £50 cup for the steer or ox, which lay between it and the Devon steer of Mr. John Wortley at Islington.

It must not be thought that undue preference is given to Shorthorns at the royal farms. On the contrary, most of the leading breeds find a place there, and the highest price realised at Her Majesty's fat stock sale on the 7th inst. was £71 for a Devon, and £60 for a Hereford. Of the Devons it may be said that they compare favourably with other breeds in quality, and are decidedly superior to the Sussex, which bear some resemblance to them. Certainly Devon beef is in high favour at the present time in the metropolitan district, and it is the boast of many a suburban butcher that he "kills" no other beef.

The great Christmas market at Islington on the 16th inst. had a total number of 5000 beasts and 11,000 sheep, or about 2000 less beasts and a thousand less sheep than were shown at the same market last year. This falling off in numbers was attributed to the fact of an over-supply which led to a serious reduction in prices last Christmas. As usual at this particular "great day," as it is termed, when close attention is paid to quality, Devons and Scotch took the lead as being in prime condition and not over-fat. Prices were considered to rule somewhat better than last year, but it cannot be said that there was any marked advance.

Butchers' and salesmen's requirements appear to have more attention paid to them than formerly. Dear-bought experience has long shown both graziers and butchers that an over-fat beast is unprofitable, and the rule holds good in reference to all animals. The best pigs for the London market are nice little porkers of an average weight of 50 lbs., and only moderately fat; yet it is notorious that there are thousands of pigs sent to London every year at a loss simply through overfeeding. At the Ipswich Show of the Suffolk Fat Cattle Club on the 16th inst. Mr. Robert Seager, who claims to be the largest buyer of pigs in the eastern counties, said some years ago he was obliged to send to the West of England for his supplies because he could not obtain near at home animals lean enough. Suffolk pigs at that time were very much too fat. He had not to send away for supplies now, but he had to be very careful in selecting them. He asked breeders to remember that the market price for fat pork now was not 3d. a

pound, while lean pork was worth 6d. or 7d. a pound. That made a great deal of difference to the breeders. Last week he had a supply, and they were too fat, so he sent half of the meat to London, because that was the only place to dispose of fat meat. The fat meat brought him 2½d. a pound, while the lean parts brought 7d. a pound.

At this Show, the champion beast was Mr. J. J. Coleman's Red Poll, which won three champion prizes as best of the Red Polls, best ox or steer, and best beast in the Show. This grand beast was also champion at the Norwich Show, and a prizewinner at Smithfield. Animals of other pure and cross-breeds were well shown, and it was a veritable triumph for the Red Polls that the breed won the championship in its own district, where it was boldly challenged by the older and more famous Polled Angus breed. A novel and admirable feature of this Show was the contest for special prizes offered by local landlords to tenants on their estates both for cattle and sheep.

WORK ON THE HOME FARM.

Farm work at midwinter is often much curtailed by broken weather, to which of late years has been added the stress of hard times, which has made so many families reduce the labour staff as much as possible every winter. Much as we regret this, it cannot, in common fairness, be expected that employment for farm labourers is to be found from purely philanthropic motives, yet it is clearly worth while seeing if more work may not be done upon farms generally in winter, without loss to the farmer at any rate. Taking corn-threshing, for example; time was when from every barn came the sound of the flail at this season of the year, and the labourer was quite assured of regular employment. The threshing machine has robbed him of much of this work, but we think the flails might still be kept going, to the mutual advantage of master and man, by paying for the threshing by the sack of corn threshed and screened ready for market. The men would earn enough for the maintenance of themselves and their families, the masters would have the unquestionable advantage of retaining the services of steady reliable men, the exodus of farm labourers to towns would cease in a great measure, and thus the best men would not be lost off the land.

Another point, too, bearing upon this important matter is the establishment of some kind of motive power at every large farm for the grinding or crushing of corn, cake, and other foods, as well as chaff cutting, root slicing and pulping, water pumping, and similar work. Horses, at any rate, may often be turned to account for such work, if only there is proper shelter for horses and gearing in the form of a roofed structure with boarded sides. This renders the farmer independent of the miller, and saves much time in sending to mills. The kindly doctrine of live and let live holds good here despite of what may be said of the miller's loss, for surely the farmer's own men claim his consideration first of all, and they will certainly have it when it so clearly accords with his interests. What is much wanted for farmers is a cheap engine, driven either by petroleum or steam, of say two-horse power, the price of which would be well within the scope of an ordinary farmer's means. We quite think the sale for such a motor would be very large, for sure we are that a hundred of them would be sold where one of the present costly engines now finds purchasers.

STORING SWEDES.—A correspondent of the *Aberdeen Free Press* describes a method of preserving Swedes, which, he says, has been a little more or less satisfactory according to the severity of the winter and has been practised in England for over half a century. It consists of drawing the Swedes by hand, and piling them into conical heaps of a large cartload each, just as they are drawn out of the ground, care being taken that the outside ones are dropped around, so that the leaves of them hang down to form a kind of thatch for receiving the earth with which they are subsequently covered. A man can easily grasp four or six in each hand according to the size of the roots. They should be dropped as much in a bunch as possible that the starting ring may be well defined. Then the Swedes nearest the ring should be thrown into it till the centre is well raised above the top of the first ring. This will admit of the second outside ring or circular layer being so formed that the necks of the roots used for it will have a downward slope, and the leaves, therefore, fall close down for forming the kind of thatch mentioned. So the heaping may be continued till the top has been formed into a sugar-loaf end. The only other care required in forming these heaps is to have the height so proportionate to the width of the bottom that the earth, which should be 4 inches deep, may not slip off after a sharp frost.

AGRICULTURAL GRANT FOR ABERDEEN.—We learn that the Board of Agriculture has intimated a grant of £300, from the sum voted by Parliament in support of agricultural education, to Mr. Thos. Jamieson, Aberdeen, in connection with the work which he is presently doing in that city and county. Of this sum £200 is for education, the balance of £100 being in aid of the agricultural research station. Last year only £50 was granted to the latter, and £100 in support of education, so that the grants have both been doubled this year. This is a tangible recognition of Mr. Jamieson's valuable services to the cause of agricultural science, which will be much appreciated by his many friends and admirers.
